(3) The Commissioner of Food and Drugs will publish a notice of the petition in the **Federal Register** announcing its availability to the public and seeking comment on the petition. The petition shall be available to the public to the extent provided under paragraph (g) of this section. The notice shall allow 30 days for comments.

(4) Within 100 days of the date of receipt of the petition that is accepted for review (i.e., that has not been found to be incomplete and subsequently returned to the petitioner), the Commissioner of Food and Drugs will:

(i) Notify the petitioner by letter of the agency's decision to grant the petitioner permission to use the proposed brand name if such use is not misleading, with any conditions or limitations on such use specified; or

(ii) Deny the petition, in which case the letter shall state the reasons therefor. Failure of the petition to fully address the requirements of this section shall be grounds for denial of the petition. Should the Commissioner of Food and Drugs not notify the petitioner of his decision on the petition within 100 days, the petition shall be considered to be granted.

(5) As soon as practicable following the granting of a petition, the Commissioner of Food and Drugs will publish a notice in the **Federal Register** informing the public of such fact.

(Information collection requirements in this section were approved by the Office of Management and Budget (OMB) and assigned OMB control number ————————)

8. Subpart F is redesignated as subpart G and new subpart F, consisting of § 101.95, is added to read as follows:

Subpart F—Specific Requirements for Descriptive Claims that are Neither Nutrient Content Claims nor Health Claims

§ 101.95 "Fresh," "freshly frozen," "fresh frozen," "frozen fresh."

The terms defined in this section may be used on the label or in labeling of a food in conformity with the provisions of this section. The requirements of the section pertain to any use of the subject terms as described in paragraphs (a) and (b) of this section that expressly or implicitly refers to the food on labels or labeling, including use in a brand name and use as a sensory modifier. However, the use of the term "fresh" on labels or labeling is not subject to the requirements of paragraph (a) of this section if the term does not suggest or imply that a food is unprocessed or unpreserved. For example, the term "fresh" used to describe pasteurized whole milk is not subject to paragraph (a) of this section because the term does not imply that the food is unprocessed (consumers commonly understand that milk is nearly always pasteurized). However, the term "fresh" to describe pasta sauce that has been pasteurized or that contains pasteurized ingredients would be subject to paragraph (a) of this section because the term implies that the food is not processed or preserved. Uses of fresh not subject to this regulation will be governed by the provisions of 403(a) of the Federal Food, Drug, and Cosmetic Act (the act).

(a) The term "fresh," when used on the label or in labeling of a food in a manner that suggests or implies that the food is unprocessed, means that the food is in its raw state and has not been frozen or subjected to any form of thermal processing or any other form of preservation, except as provided in paragraph (c) of this section.

(b) The terms "fresh frozen" and "frozen fresh," when used on the label or in labeling of a food, mean that the food was quickly frozen while still fresh (i.e., the food had been recently harvested when frozen). Blanching of the food before freezing will not preclude use of the term "fresh frozen" to describe the food. "Quickly frozen" means frozen by a freezing system such as blast-freezing (sub-zero Fahrenheit temperature with fast moving air directed at the food) that ensures the food is frozen, even to the center of the food, quickly and that virtually no deterioration has taken place.

(c) *Provisions and restrictions*—(1) The following do not preclude the food from use of the term "fresh:"

(i) The addition of approved waxes or coatings;

(ii) The post-harvest use of approved pesticides;

(iii) The application of a mild chlorine wash or mild acid wash on produce; or

(iv) The treatment of raw foods with ionizing radiation not to exceed the maximum dose of 1 kiloGray in accordance with § 179.26 of this chapter.

(2) A food meeting the definition in paragraph (a) of this section that is refrigerated is not precluded from use of "fresh" as provided by this section.

Dated: December 17, 1992.

Food and Drug Administration

21 CFR Part 105

[Docket No. 91N–384L]

RIN 0905–AD08

Food Labeling: Label Statements on Foods for Special Dietary Use

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is amending the food labeling regulations to conform them to the requirements of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). With the passage of the 1990 amendments to the Federal Food, Drug, and Cosmetic Act (the act), certain provisions concerning label statements on foods for special dietary use in reducing or maintaining caloric intake or body weight are no longer appropriately included in that regulation but are now more appropriately defined as nutrient content claims applicable to the general population and regulated under 21 CFR part 101. FDA is making changes in 21 CFR 105.66 to reflect this fact. FDA is also announcing its intention to reexamine 21 CFR part 105 and revise that part as necessary to ensure that it provides appropriate coverage for foods for special dietary use.

DATES: Effective May 8, 1994, except as to any provisions that may be stayed by the filing of proper objections; written objections and requests for a hearing by February 5, 1993.

ADDRESSES: Written objections may be sent to the Dockets Management Branch (HFS–155), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857.

FOR FURTHER INFORMATION CONTACT: Elizabeth J. Campbell, Center for Food Safety and Applied Nutrition (HFS–155), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–5229.

SUPPLEMENTARY INFORMATION:

I. Background

In the **Federal Register** of November 27, 1991 (56 FR 60421), FDA published a proposed rule entitled "Food Labeling: Nutrient Content Claims, General Principles, Petitions, Definition of Terms" (the general principles proposal) that would, among other things, establish general principles for the use of claims describing the nutrient content of a food and define certain specific nutrient content claims that can be used to describe the levels of certain nutrients in a food.

The general principles proposal was issued in response to the 1990 amendments (Pub. L. 101–535) to the act. With respect to nutrient content claims, the 1990 amendments amended the act by adding section 403(r)(1)(A) (21 U.S.C. 343(r)(1)(A)) which states that a food is misbranded if it bears a claim in its label or labeling that either expressly or implicitly characterizes the level of any nutrient of the type required to be declared as part of the nutrition labeling, unless such claim is made using terms which are defined in regulations adopted by the agency under section 403(r)(2).

The proposed regulations on nutrient content claims included provisions similar or identical to some provisions in § 105.66, which addresses foods for special dietary use in reducing or maintaining caloric intake or body weight. Therefore, the general principles proposal included several changes in § 105.66 to eliminate redundancy in the regulations and to conform § 105.66 to the 1990 amendments. Specifically, FDA proposed to redesignate requirements for terms such as "low calorie" and "reduced calorie," for other comparative calorie claims, and for sugar claims from § 105.66 to new § 101.60, which defines terms used to make nutrient content claims for the calorie content of foods. This redesignation is necessary because terms such as "low calorie" and "reduced calorie" are no longer appropriately regulated under the regulations for foods for special dietary use but are now more appropriately defined under the 1990 amendments as nutrient content claims for foods intended for use by the general population. FDA also proposed to delete from § 105.66 any inappropriate reference to specific nutrient content claims or similar terms and any statement that is inconsistent with the 1990 amendments.

FDA also proposed to delete the exemption (§ 105.66(e)(3)) for formulated meal replacements and other foods that are represented for special dietary use as a whole meal from the requirements in § 105.66(e)(1). These requirements bear on the use of label terms that suggest usefulness as low calorie or reduced calorie foods, such as "diet," "dietetic," "artificially sweetened," and "sweetened with nonnutritive sweetener." FDA proposed to remove this exemption so that such claims could be expressly permitted under § 105.66, and thus not be prohibited as implied nutrient content claims under the 1990 amendments, until more appropriate regulations can be issued. The agency stated its view that claims that are permitted under § 105.66 meet the requirements of section 403(r) of the act (56 FR 60421 at 60458).

FDA noted in the proposal that a significant portion of § 105.66 remains appropriate for regulating foods that are for special dietary use (56 FR 60421 at 60457). Such foods are those that are specifically represented as, or that purport to be, useful as part of a weight control plan, as opposed to those that are simply represented as being low or reduced in calories (although products low or reduced in calories can be useful in reducing or maintaining body weight). The agency did not propose to remove the remaining portion of § 105.66, which includes requirements for label statements about nonnutritive sweeteners and for the use of the term "diet" and related terms. FDA noted, however, that it plans to reexamine the provisions remaining in § 105.66 and initiate additional rulemaking as appropriate (56 FR 60421 at 60457).

FDA is publishing a final rule based on the general principles proposal and on a related proposal (56 FR 60421 at 60478, November 27, 1991) concerning nutrient content claims related to the fat, fatty acid, and cholesterol content of food elsewhere in this issue of the **Federal Register**. This final rule effecting revisions in § 105.66 is being published as a separate document because § 105.66 was issued under the authority of section 403(j) of the act. Thus, revisions to § 105.66 must be made in accordance with the formal rulemaking procedures in section 701(e) of the act (21 U.S.C. 371(e)). Under these procedures, there is an opportunity to object to the provisions of a final rule and to request a public hearing on that objection. Such an opportunity is not provided as part of the notice and comment procedures apply to that most of the rest of the rulemaking that FDA is doing in response to the 1990 amendments.

The agency received only a few comments in response to the proposed revisions in § 105.66. Some of the comments received by the agency addressed matters concerning other regulations in 21 CFR part 105 (i.e., §§ 105.62 and 105.67) which are outside the scope of this rulemaking and are not being addressed here. However, after review of these comments, FDA believes that other regulations in part 105 may need to be reexamined, and that additional rulemaking may need to be initiated to ensure that these regulations

fully address their subject matter. In its reexamination of § 105.66, FDA will consider among other things, whether that regulation adequately describes foods for use in reducing or maintaining body weight, such as formulated meal replacements, whether it appropriately provides for use of terms such as "diet" on such foods, and whether "artificially sweetened" or "sweetened with a nonnutritive sweetener" should be included as label terms suggesting usefulness as low calorie or reduced calorie foods. These actions will be undertaken at some time in the future and FDA will solicit comments on the relevant issues at that time.

All of the relevant comments on proposed revisions in § 105.66 supported FDA's intent to revise this regulation to conform it to the provisions of the 1990 amendments. However, some of the comments raised concerns about some of the specific actions that FDA proposed. These comments are addressed below.

II. Comments and Agency Response

1. One comment asserted that requiring formulated meal replacements that bear terms such as "diet," "dietetic," "artificially sweetened," and "sweetened with nonnutritive sweetener" to meet the requirements for low or reduced calorie foods, or to make another comparative calorie claim, would effectively ban the sale of these foods. The comment stated that formulated meal replacements do not meet the definition of "low calorie" or "reduced calorie," and that a "reference" food would have to be identified to make a "reduced calorie" or other comparative calorie claim. The comment pointed out that FDA did not address what the reference food should be for formulated meal replacements. The comment requested that FDA provide in the regulations that a formulated meal replacement or other food that is represented to be of special dietary use as a whole meal, and that bears terms such as "diet," "dietetic," "artificially sweetened," or "sweetened with nonnutritive sweetener," not be required to be a "low calorie" or "reduced calorie" food, or to bear another comparative calorie claim, if its labeling is not false or misleading, and the product is useful as part of a weight loss or weight control program.

As noted above, FDA had proposed to delete the exemption in § 105.66(e)(3) for formulated meal replacements and other foods that are represented to be of special dietary use as a whole meal, from the requirements in § 105.66(e)(1) so that such foods would be expressly authorized to make "diet," "dietetic," or "artificially sweetened" claims under § 105.66. Thus, these claims on these foods would not be prohibited as unauthorized implied nutrient content claims under the 1990 amendments. However, FDA has reconsidered the circumstances under which claims should be regarded as implied nutrient content claims and as claims for special dietary use. As stated in the final rule on nutrient content claims, published elsewhere in this issue of the **Federal Register**, the agency does not consider claims made solely to portray the usefulness of a food for supplying a particular dietary need that exists by reason of a physical, physiological, pathological, or other condition, as described in part 105, to be a nutrient content claim subject to § 101.13. On the other hand, a claim of dietary usefulness made in a context that is relevant to the general population (e.g., where the label states that the food is "low calorie") would be subject to the requirements for nutrient content claims. FDA views a claim such as "use as part of a weight reduction program," made in conjunction with terms such as "diet," "dietetic," "artificially sweetened," or "sweetened with nonnutritive sweetener," on a formulated meal replacement to be a claim that solely portrays the usefulness of the food for a special dietary need, as described in part 105. Thus, such a claim by itself, without any other reference to nutrient aspects of the food relative to the general population, is not a nutrient content claim. Therefore, FDA concludes that there is no need to subject formulated meal replacements to the requirements of § 105.66(e)(1) to preclude claims such as "diet" on such products from being prohibited as implied nutrient content claims.

FDA, thus, has decided not to delete § 105.66(e)(3) and thus will continue to permit formulated meal replacements and other foods that are represented to be of special dietary use as whole meals to use terms such as "diet," "dietetic," "artificially sweetened," and "sweetened with nonnutritive sweetener" on their labels and labeling without having to comply with the requirements of § 105.66(e)(1). Therefore, the concern raised that formulated meal replacements are unable to comply with the requirements of § 105.66(e)(1) is moot.

However, FDA advises that the use of terms such as "diet," "dietetic," "artificially sweetened," and "sweetened with nonnutritive sweetener" on the label or in the labeling of any food, including a food for special dietary use, is subject to the act's general prohibition against false or misleading labeling in section 403(a) of the act. Thus, FDA can take action against any false or misleading use of a term such as "diet." For example, if a food that is not a formulated meal replacement purported on its label to be a formulated meal replacement to avoid the requirement that foods using the label term "diet" either be low in calories, reduced in calories or bear another comparative calorie claim, FDA would consider the food to be misbranded because it is falsely represented as a formulated meal replacement. Such a food would also be in violation of § 105.66(e)(1) because it is not a formulated meal replacement. FDA is likely to take action against any food that uses terms such as "diet," "dietetic," "artificially sweetened," and "sweetened with nonnutritive sweetener" on its label or in its labeling in this manner.

2. A comment stated that FDA should amend § 105.66(e)(1) in the final rule to clarify that this regulation applies only when the specific terms "diet," "dietetic," "artificially sweetened," and "artificially sweetened with nonnutritive sweetener" appear on the label as self-contained terms, but not when a term such as "diet" is used in a statement that represents the product to be useful as part of a weight loss "diet." The comment stated that the proposal could be misunderstood to mean that FDA is prohibiting the use of all other claims suggesting that a product is useful in a weight loss "diet" if that product does not meet the definition for "low calorie" or "reduced calorie." The comment stated that such an interpretation would be inconsistent with FDA's express intention of permitting such claims as stated in the final rule establishing § 105.66 (43 FR 43248 at 43253, September 22, 1978), wherein the agency stated:

> * * * any food may make a claim of special dietary usefulness for weight control on some basis other than its being "low calorie," "reduced calorie," or comparatively useful * * *. The claim must not be misleading and the basis for the claim must be conspicuously and clearly stated in conjunction with the claim. These foods may make appropriate claims, e.g., "for calorie restricted diets" or "useful for weight control."

The agency advises that it continues to hold the position that it stated in the final order establishing § 105.66. In that rulemaking, FDA stated that a food that purports to be useful for weight control on some other basis than its being "low calorie," "reduced calorie," or comparatively useful in controlling calorie intake is subject to the provisions of § 105.66(a) and (b) but not § 105.66(e). The agency stated that to

comply with § 105.66(a) and (b), such foods must bear nutrition labeling, labeling about the presence of nonnutritive ingredients, and a conspicuous and nonmisleading statement about the basis of the claim (43 FR 43248 at 43253, September 22, 1978).

Concerning the matter raised by the comment, i.e., the use of statements incorporating the term "diet" on foods for special dietary use intended for weight reduction, the agency concludes that such statements do not invoke the requirements of § 105.66(e), except when made on meal replacements or other foods represented to be of special dietary use as a whole meal, which are subject to § 105.66(e)(3), when they are used in a manner that does not suggest that the food is a "low calorie" or "reduced calorie" food. Such foods are subject to the requirements of § 105.66(a) and (b). However, the revision of the regulation sought by this comment, i.e., a provision in the regulation clarifying the circumstances where § 105.66(e) applies, is beyond the scope of this rulemaking. FDA stated in the general principles proposal that it only intended to make changes in § 105.66 at this time that are necessary to conform this section to the 1990 amendments. FDA will fully consider any necessary clarification of § 105.66(e)(1) in this regard when it initiates additional rulemaking on this section as stated above.

3. One comment suggested that the "Weight Watchers" line of foods falls within the provisions of § 105.66 because it provides information on the product label that suggests that these products can be useful in an overall weight-control diet plan. In addition, this same comment expressed concern that use of the brand name "Weight Watchers" would be prohibited on those products introduced into the marketplace after October 25, 1989, i.e., the date after which products introduced into the marketplace that make nutrient content claims in their brand names must use terms in the claims that are defined by the agency in a regulation, or that have been approved by the agency in response to a petition (section 403(r)(2)(A)(i), (r)(2)(C), and (r)(4)(A)(iii) of the act).

FDA advises that, in general, it would regard a brand name such as "Weight Watchers," when accompanied by information on the product label that suggests that the product can be useful in an overall weight-control diet plan, without any other reference to nutrient aspects of the food relative to the general population, to be a claim that solely portrays the usefulness of the food for a special dietary need as described in part 105 (see comment 1 of this document). Under these circumstances, such a claim is subject to the provisions of § 105.66 and is not a nutrient content claim. Accordingly, such a claim in a brand name may continue to be used on such products irrespective of whether a specific product under that brand name was introduced into the marketplace before October 25, 1989.

III. Conclusions

After review and consideration of the comments received in response to the November 27, 1991, proposal, FDA concludes that no evidence or information has been presented that would alter the agency's tentative determination that it should amend § 105.66 to conform that regulation to the provisions of the 1990 amendments. Therefore, FDA is amending § 105.66 as proposed with the exception of the revision in the final rule discussed in comment 1 of this document. FDA has also corrected two inadvertent errors that appeared in the proposal in the codified text of paragraph (e)(1). First, the proposed text omitted the words "such as" that had immediately preceded "diet," "dietetic," "artificially sweetened," or "sweetened with nonnutritive sweetener" in the existing regulation. It was not the agency's intent to delete these words from the revised text, and thus, they are being restored in the final rule. Secondly, FDA has conformed paragraph (e)(1) with respect to comparative calorie claims to paragraph (d). FDA has also made other minor editorial revisions in the text of the final rule for internal consistency.

IV. Environmental Impact

The agency has previously considered the environmental effects of this rule as announced in the general principles proposal (56 FR 60467). At that time, FDA determined under § 25.24(a)(11) that the actions proposed therein (which include this action) are of a type that do not individually or cumulatively have a significant impact on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement was required.

4. Several comments on the general principles proposal suggested that there would be significant adverse environmental effects from the actions proposed therein because they would cause large stocks of labels and labeled packaging materials to be discarded and require a great number of trees to be harvested to provide new labeling material. One comment estimated the number of label units from the dairy industry that would need to be discarded following publication of FDA's final rules on several food labeling actions, including this action. However, this comment did not: (1) Show how these estimates were derived, (2) identify what portion of the estimated amounts are attributable to this action, or (3) describe what impact the discarded labeling and packaging would have on the disposal of solid waste.

Neither the 1990 amendments nor FDA's proposed regulations require a food company to make nutrient content claims on its product labels. Food companies have known since November 8, 1990, the date of enactment of the 1990 amendments, that possibly by May 8, 1993, their labels would not be able to include nutrient content claims unless the claims conformed to FDA's regulations. In the general principles proposal (56 FR 60421) the agency proposed that this final rule would become effective 6 months after its date of publication in the **Federal Register**. However, the agency has determined that this final rule will become effective May 8, 1994. FDA believes that this effective date will allow ample time for food companies to use up most of the label and packaging stocks that existed on November 8, 1990, and that contained nutrient content claims. Consequently, the comments on the potential for adverse environmental effects do not affect the agency's previous determination that no significant impact on the human environment is expected, and that an environmental impact statement is not required.

V. Economic Impact

In accordance with the Regulatory Flexibility Act (Pub. L. 96–354), FDA has reviewed the final rule to redesignate certain requirements in § 105.66 to § 101.60 to determine its impact on small entities, including small businesses. Although the food labeling reform initiative taken as a whole, would result in a major rule, FDA has determined that redesignating certain requirements in § 105.66 to § 101.60 for conformance to the 1990 amendments, will not result in a significant impact on a substantial number of small entities. FDA has not received any new information or comments that would alter this determination. Therefore, FDA certifies in accordance with the Regulatory Flexibility Act, that no significant impact on a substantial number of small entities will derive from this action.

In accordance with Executive Order 12291, FDA has carefully analyzed the economic effects of this final rule, and the agency has determined that the rule, if promulgated, will not be a major rule as defined by that order.

VI. Objections

Any person who will be adversely affected by this regulation may at any time on or before December 10, 1992, file with the Dockets Management Branch (address above) written objections thereto. Each objection shall be separately numbered, and each numbered objection shall specify with particularity the provisions of the regulation to which objection is made and the grounds for the objection. Each numbered objection on which a hearing is requested shall specifically so state. Failure to request a hearing for any particular objection shall constitute a waiver of the right to a hearing on that objection. Each numbered objection for which a hearing is requested shall include a detailed description and analysis of the specific factual information intended to be presented in support of the objection in the event that a hearing is held. Failure to include such a description and analysis for any particular objection shall constitute a waiver of the right to a hearing on the objection. Three copies of all documents shall be submitted and shall be identified with the docket number found in brackets in the heading of this document. Any objections received in response to the regulation may be seen in the Dockets Management Branch between 9 a.m. and 4 p.m., Monday through Friday. FDA will publish notice of the objections that the agency has received or lack thereof in the Federal Register.

List of Subjects in 21 CFR Part 105

Dietary foods, Food grades and standards, Food labeling, Infants and children.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 105 is amended as follows:

PART 105—FOODS FOR SPECIAL DIETARY USE

1. The authority citation for 21 CFR part 105 continues to read as follows:

Authority: Secs. 201, 401, 403, 409, 411, 701, 706 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 341, 343, 348, 350, 371, 376).

2. Section 105.66 is revised to read as follows:

§ 105.66 Label statements relating to usefulness in reducing or maintaining body weight.

(a) *General requirements.* Any food that purports to be or is represented for special dietary use because of usefulness in reducing or maintaining body weight shall bear:

(1) Nutrition labeling in conformity with § 101.9, or, where applicable, § 101.36 of this chapter, unless exempt under that section; and

(2) A conspicuous statement of the basis upon which the food claims to be of special dietary usefulness.

(b) *Nonnutritive ingredients.* (1) Any food subject to paragraph (a) of this section that achieves its special dietary usefulness by use of a nonnutritive ingredient (i.e., one not utilized in normal metabolism) shall bear on its label a statement that it contains a nonnutritive ingredient and the percentage by weight of the nonnutritive ingredient.

(2) A special dietary food may contain a nonnutritive sweetener or other ingredient only if the ingredient is safe for use in the food under the applicable law and regulations of this chapter. Any food that achieves its special dietary usefulness in reducing or maintaining body weight through the use of a nonnutritive sweetener shall bear on its label the statement required by paragraph (b)(1) of this section, but need not state the percentage by weight of the nonnutritive sweetener. If a nutritive sweetener(s) as well as nonnutritive sweetener(s) is added, the statement shall indicate the presence of both types of sweetener, e.g., "Sweetened with nutritive sweetener(s) and nonnutritive sweetener(s)."

(c) *"Low calorie" foods.* A food purporting to be "low calorie" must comply with the criteria set forth for such foods in § 101.60(b)(2) and (b)(3) of this chapter.

(d) *"Reduced calorie" foods and other comparative calorie claims.* A food purporting to be "reduced calorie" or otherwise containing fewer calories than a reference food must comply with the criteria set forth for such food in § 101.60(b)(4) and (b)(5) of this chapter.

(e) *Label terms suggesting usefulness as low calorie or reduced calorie foods.* (1) Except as provided in paragraphs (e)(2) and (e)(3) of this section, and in § 101.13(q)(2) of this chapter for soft drinks, a food may be labeled with terms such as "diet," "dietetic," "artificially sweetened," or "sweetened with nonnutritive sweetener" only if the claim is not false and misleading, and the food is labeled "low calorie" or "reduced calorie" or bears another comparative calorie claim in compliance with part 101 of this chapter and this section.

(2) Paragraph (e)(1) of this section shall not apply to any use of such terms that is specifically authorized by regulation governing a particular food, or, unless otherwise restricted by regulation, to any use of the term "diet" that clearly shows that the food is offered solely for a dietary use other than regulating body weight, e.g., "for low-sodium diets."

(3) Paragraph (e)(1) of this section shall not apply to any use of such terms on a formulated meal replacement or other food that is represented to be of special dietary use as a whole meal, pending the issuance of a regulation governing the use of such terms on foods.

(f) *"Sugar free," and "no added sugar."* Criteria for the use of the terms "sugar free" and "no added sugar" are provided for in § 101.60(c) of this chapter.

Dated: October 22, 1992.

21 CFR Part 130

[Docket No. 91N–0317 et al.]

RIN 0905–AD08

Food Standards: Requirements for Foods Named by Use of a Nutrient Content Claim and a Standardized Term

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is amending the General Provisions for food standards to prescribe a general definition and standard of identity for foods named by use of a nutrient content claim defined in part 101 (21 CFR part 101) (such as "fat free," "low calorie," and "light") in conjunction with a traditional standardized name (for example "reduced fat sour cream"). FDA is taking this action to assist consumers in maintaining healthy dietary practices by providing for modified versions of certain standardized foods that bear descriptive names that are meaningful to consumers. FDA believes that this action will promote honesty and fair dealing in the interest of consumers. This rule applies only to standards of identity and not to standards of quality or fill.

EFFECTIVE DATE: May 8, 1994.

FOR FURTHER INFORMATION CONTACT: Shellee A. Davis, Center for Food Safety and Applied Nutrition (HFS–158), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–5112.

SUPPLEMENTARY INFORMATION:

I. Background

One of the main purposes of the Nutrition Labeling and Education Act of 1990 (Pub. L. 101–535) (the 1990 amendments) was to establish the circumstances in which claims could be made that describe the nutrient content of food. In response to the requirements of the 1990 amendments, elsewhere in this issue of the **Federal Register**, in a document entitled "Food Labeling: Nutrient Content Claims, General Principles, Petitions, Definitions of Terms" (hereinafter referred to as the nutrient content claims final rule), FDA is establishing in part 101 definitions for such nutrient content claims together with general principles and procedures governing their use.

In the **Federal Register** of November 27, 1991 (56 FR 60512), FDA published a proposal to amend the General Provisions for food standards to prescribe a general definition and standard of identity for foods named by use of a nutrient content claim defined in part 101 (e.g., "fat free," "low calorie," and "light") in conjunction with a traditional standardized name (e.g., "reduced fat sour cream"). Interested persons were given until February 25, 1992, to comment on the proposed regulation.

FDA received approximately 200 responses, each of which contained one or more comments, from trade and retail associations, government organizations, manufacturers, consumers, retailers, consumer groups, State groups, private organizations, professional societies, and universities. The comments generally supported the proposal. Several comments addressed issues outside the scope of the proposal (e.g., serving size and nutrition labeling) that will not be discussed here. A number of comments suggested modification and revision in various provisions of the proposal. A summary of the suggested changes and the agency's responses follow.

II. Requirements for Foods Named by Use of a Nutrient Content Claim and a Standardized Term Under the 1990 Amendments

A. General Comments

1. Appropriateness and Need for Regulation

In the proposal, FDA invited comments with respect to the appropriateness and need for a general standard in proposed § 130.10 to establish the requirements for modified foods named by use of a nutrient content claim and a standardized term (56 FR 60512 at 60517).

1. Several comments stated that it is important to keep the present standards of identity as they are. One comment stated that, while allowing for the establishment of standards of identity for products like "light sour cream" and "lowfat ice cream," FDA must ensure that the existing standards for "milk," "sour cream," "ice cream," or "butter" are not diluted or debased. These comments stated that under no circumstances should a product that has undergone any form or degree of defatting be allowed to be called simply "milk," "sour cream," or "ice cream."

The agency agrees with these comments. FDA is not amending any of the existing standards of identity with this regulation. Under section 403(g) of the Federal Food, Drug, and Cosmetic Act (the act) (21 U.S.C. 343(g)), a food is misbranded if it purports to be or is represented as a food for which a definition and standard of identity has been prescribed by regulation, unless it conforms to such definition and standards.

Elsewhere in this issue of the **Federal Register**, FDA is publishing a final rule entitled "Food Labeling: Use of Nutrient Content Claims for Butter Products," which adds new § 101.67. Except as provided in new § 101.67 for "butter," any food whose name includes a standardized term must conform to the standard of identity for that food found in parts 131 through 169 (21 CFR parts 131 through 169) or in new § 130.10. For example, a food labeled as "ice cream" must conform to the standard for ice cream in § 135.110, or it is misbranded. Similarly, a food labeled as "lowfat ice cream" must comply with new § 130.10. New § 130.10(a) states that the nutrient content claim must comply with the requirements of § 101.13 and with the requirements of the regulations in part 101 that define the particular nutrient content claim that is used. Thus, use of the term "lowfat" on a label for "lowfat ice cream" must comply with § 101.13 and § 101.62(b)(2) (i.e., the food must contain 3 grams (g) or less of fat per serving and per 50 g of food). New § 130.10(a) also provides that the "lowfat ice cream" must comply with the relevant standard in all other respects (e.g., major ingredients and the freezing process) except as provided in new § 130.10(b), (c), and (d).

2. One comment expressed concern that each modified food permitted to use a standardized food name meet consumer expectations. The comment suggested that if consumers no longer want or expect standardized products to have certain characteristics, the standards should be changed.

FDA appreciates the concern expressed by the comment. Section 401 of the act (21 U.S.C. 341) gives the agency authority to establish definitions and standards of identity for foods whenever such action will promote honesty and fair dealing in the interest of consumers. FDA has traditionally established individual standards to provide consumers with foods that include a modifier, such as a nutrient content claim or some other descriptive term, and a standardized term in their name. For example, the agency has established a standard of identity for milk in § 131.110 (21 CFR 131.110), but there are 17 other standards in part 131 (21 CFR part 131) that use the term "milk" in the name of the food (e.g., "cultured milk" (§ 131.112), "evaporated milk" (§ 131.130), and "skim milk" (§ 131.143)). FDA does not believe that use of these modifiers with

the term "milk" is confusing to consumers because these terms are defined by the standards.

FDA believes that establishing a general definition and standard of identity for modified versions of standardized foods that qualify for use of a nutrient content claim is a more efficient way to provide consumers with these foods than having to issue temporary marketing permits to each manufacturer desiring to market test a new modified food and, ultimately, establishing individual new food standards for each new modified version. New § 130.10 provides that the nutrient content claims that are used with standardized terms must be defined by FDA regulation. The food must comply with the nutrient content claim definition and with the requirements in new § 130.10 concerning performance characteristics, addition of nutrients and other ingredients, and labeling. Such requirements will ensure not only that a "lowfat" version of a standardized food is low in fat, but also that the food appropriately bears the standardized name. Therefore, FDA concludes that use of nutrient content claims with a standardized name will promote honesty and fair dealing in the interest of consumers.

2. Scope of Regulation

3. One comment stated that it presumed that the agency did not intend that proposed § 130.10 be mandatory.

FDA advises that the comment's presumption is incorrect, at least to the extent that a firm wants to make a food under the provisions of new § 130.10. The agency is establishing a general definition and standard of identity for such foods. Section 403(g) of the act states that a food is misbranded if it purports to be or is represented as a food for which a definition and standard of identity has been prescribed by regulations as provided by section 401 of the act, unless it conforms to such definition and standard, and its label bears the name of the food specified in the definition and standard. Therefore, modified foods that conform to the definition and standard established in new § 130.10 must be labeled with the name provided under new § 130.10 or be misbranded under section 403(g) of the act. For example, sour cream must contain not less than 18 percent milkfat (§ 131.160). A sour cream product containing 12 percent milkfat and conforming to the standard of identity for sour half-and-half (§ 131.185) must be labeled in compliance with § 131.185(d) as either "sour half-and-half" or "cultured sour half-and-half." A sour cream product containing 9 percent milkfat that conforms to new § 130.10 and to the definition of "light" in § 101.56 must be labeled as "light sour cream."

4. One comment stated that proposed § 130.10(a) should be revised to make the intended scope of the regulation explicit. It stated that, as written, proposed § 130.10(a) creates an undesirable ambiguity with respect to foods that substitute for standardized foods that are themselves substitutes for one another (e.g., butter and margarine or cream cheese and neufchatel cheese). The comment suggested that FDA revise the language of proposed § 130.10(a) to limit the scope of proposed § 130.10 to "foods that substitute for a standardized food * * * and that use the name of that standardized food in their statement of identity but that do not comply * * *." The comment noted that a statement in the preamble limited the intended scope of proposed § 130.10 to substitute foods whose statement of identity includes the name of a standardized food. The comment added that an alternative way to solve the problem would be to provide in proposed § 130.10(a) that, in the case of a food that substitutes for more than one standardized food, the modified food needs to comply with proposed § 130.10 only with respect to one standardized food.

The agency agrees with the comment. Foods that comply with any standard of identity established in parts 131 through 169, are not subject to new § 130.10, even if they would qualify for a nutrient content claim as a modified version of a standardized food (e.g., sour half-and-half (§ 131.185) cannot be labeled as reduced fat sour cream under new § 130.10). However, foods that do not comply with a standard, that are modified versions of standardized foods, that qualify for use of a nutrient content claim, and that use the traditional standardized name in their statement of identity are the standardized foods that are defined by new § 130.10. This is consistent with the approach that FDA took in the proposal (56 FR 60512).

The agency has been persuaded by the comment that new § 130.10(a) should be revised to limit the scope of the regulation. Therefore, FDA is revising new § 130.10(a), as requested by the comment, to state: "* * * foods that substitute for a standardized food * * * and that use the name of that standardized food in their statement of identity but that do not comply * * *." In addition, FDA is revising the title of the regulation to delete the term "substitute" because new § 130.10 applies only to a certain category of substitute foods and not to all types of substitute foods as defined under §§ 101.3(e)(4) and 101.13(d). FDA believes that these revisions will more clearly establish the scope of the regulation and eliminate confusion as to foods that may substitute for other foods in a more general sense. Therefore, FDA concludes that these revisions will promote honesty and fair dealing in the interest of consumers.

FDA also agrees with the comment that in the case of a food that qualifies as a modified version of more than one standardized food, the food must be named under new § 130.10 only with reference to one standardized food. The § 130.10 product is a substitute for the standardized food that is named in its statement of identity. For example, cream cheese is defined in § 133.133 (21 CFR 133.133) as a product containing at least 33 percent milkfat by weight of the cream cheese. Neufchatel cheese (§ 133.162 (21 CFR 133.162)) is a product similar to cream cheese except that the milkfat content is not less than 20 percent but less than 33 percent by weight of the finished food. A reduced fat cream cheese-type product containing 15 percent milkfat may be considered a modified version of either cream cheese or neufchatel cheese because it contains at least 25 percent less fat than either food. Under new § 130.10, if the product is called "reduced fat cream cheese," it is a modified version of "cream cheese" because "cream cheese" is the standardized term used in conjunction with the nutrient content claim. If the product is called "reduced fat neufchatel cheese," it is a modified version of "neufchatel cheese."

5. One comment asked how this regulation would affect the nonstandard substitute cheese category (e.g., cheese containing vegetable oil in place of milkfat). It also asked if the regulations regarding "imitation" and "substitute" foods cited in § 101.3(e) would remain intact, or if this regulation would trigger the development of new requirements.

This final rule only sets forth the requirements for certain modified versions of standardized foods that qualify for the use of a nutrient content claim. Foods that do not use a traditional standardized term but use a nutrient content claim must comply with the general requirements of § 101.13 and the specific requirements for the particular nutrient content claim as well as the other provisions on common or usual names (§ 102.5 (21 CFR 102.5)). A modified food that does use a traditional standardized term but that does not comply with the traditional standard of identity or with

new § 130.10 must be labeled either as an "imitation," if it is nutritionally inferior, or as a "substitute," "alternative," or other appropriate term, if it is not nutritionally inferior, as specified in § 101.3(e) which will remain in effect. For example, a mozzarella cheese product made with skim milk and vegetable oil does not comply with the standard for mozzarella cheese (§ 133.155) or with new § 130.10(d)(2) and, therefore, must be labeled as "imitation mozzarella cheese" if nutritionally inferior to mozzarella cheese or as "mozzarella cheese alternative" or "mozzarella cheese substitute" if it is not nutritionally inferior. For this reason, FDA concludes that there is no need to amend the definitions for "imitation" or "substitute" foods in § 101.3(e) at this time.

6. One comment stated that there should be some listing of the standards as to which proposed § 130.10 is intended to apply. It stated that there was uncertainty as to when a particular food is subject to the general rule or requires individual agency action. Another comment stated that there is no reason to exclude any category of standardized foods from this proposal and urged FDA to retain the general applicability of the generic standard to all standardized foods in the final rule.

The agency disagrees that it needs to establish a specific list of standards to which new § 130.10 is to apply. New § 130.10(a) states that the foods prescribed by this general definition and standard of identity are those foods that substitute for a standardized food defined in parts 131 through 169. Thus, a modified version of any food defined by a standard of identity would be subject to new § 130.10, and no more specificity in new § 130.10 is necessary. This generic standard will minimize the need to establish individual new standards or to amend existing standards. FDA will establish new standards or amend existing ones if it determines that such action is necessary to promote honesty and fair dealing in the interest of consumers.

However, FDA notes that at the present time some standardized foods that are merely processed (e.g., canned green beans and canned wax beans (§ 155.120 (21 CFR 155.120)), tomato juice (§ 156.145 (21 CFR 156.145)), canned oysters (§ 161.145 (21 CFR 161.145))) cannot be modified so that the food does not comply with the traditional standard of identity, although they may still qualify to bear a defined nutrient content claim. For example, salt is an optional ingredient in the standard of identity for canned green beans and canned wax beans (§ 155.120). Therefore, if the product contains no added salt, the product remains the standardized food under § 155.120 and outside the scope of new § 130.10, although it may still qualify to bear a "no added salt" claim.

B. Product Deviations

In the proposal, FDA requested comments concerning how far a product may deviate from a standard and still qualify for use of the standardized name (56 FR 60512 at 60518).

7. Several comments stated that it is unnecessary for FDA to try to establish specific, quantitative limits. One comment stated that the agency should apply the general criteria for determining whether a food is a "substitute" for a standardized food. It stated that those criteria, which have been developed primarily through case law over the years, are based on everyday characteristics of the food that would be significant to the consumer, such as taste, texture, and appearance. Importantly, such an approach would conform to the President's directive, which requires regulations to use performance standards, not command-and-control techniques.

Several comments urged the agency to establish guidelines as to how much a modified food can deviate from the standardized product and still comply with proposed § 130.10.

The agency agrees that general requirements as to how far a modified food may deviate from the standard of identity and still use the standardized name are necessary. FDA also acknowledges that general criteria concerning significant characteristics of foods that are important to consumers have been developed primarily through case law, and the agency will use these criteria as needed for enforcement purposes. Some general requirements were included in the proposal and are now mandated by new § 130.10. A § 130.10 food must not be nutritionally inferior to the standardized food (new § 130.10(b)) and must have similar performance characteristics as the standardized food, including physical properties, flavor characteristics, functional properties, and shelf life (new § 130.10(c)).

In addition, under new § 130.10(d)(1), ingredients mandated to be present in a food by a standard of identity must also be present in the § 130.10 food. FDA believes that consumers expect certain ingredients to be present in specific foods. For example, the agency believes that consumers expect that a product such as "light mayonnaise" contains a significant amount of vegetable oil and egg yolk because these ingredients are required to be present in regular mayonnaise (§ 169.140). Thus, FDA has added new § 130.10(d)(4) to require that mandated ingredients must be present in a significant amount if the food is to be considered a modified version of the traditional standardized food. A significant amount is defined in that paragraph as at least that amount of the ingredient that is necessary to achieve the technical effect that the ingredient provides to the traditional standardized food. FDA concludes that this requirement in new § 130.10(d)(4) will promote honesty and fair dealing in the interest of consumers because it will ensure that a § 130.10 food will bear an appropriate relationship to the traditional standardized food.

8. One comment requested that FDA recognize that the removal of sugar and calories from a juice would result in a product that is still juice (e.g., "reduced calorie orange juice" or "light orange juice"). It added that the principles for naming products that are nutritionally modified versions of standardized products should be no different for standardized juices than for other standardized products. The comment requested that FDA ensure that this regulation is consistent with the regulation on percent juice labeling.

FDA agrees that the principles for naming products that are modified versions of standardized juice products should be no different than for other modified products. The agency recognizes that the reduction of sugars from a juice, and the subsequent sweetening of the product with a safe and suitable sweetener that provides an insignificant amount of calories, results in a modified juice product. Use of a sweetener with the same caloric density as the sugar naturally present in the juice is prohibited under new § 130.10(d)(2) because it would be replacing the sugar component of the juice with a similar ingredient from another source. For example, sucrose and glucose that have been removed from orange juice (§ 146.135 (21 CFR 146.135)) could not be replaced with fructose even though fructose is sweeter than the sucrose and glucose that are naturally present in orange juice. If, on the other hand, the product has been reduced in sugars so that it qualifies for use of a nutrient content claim and complies in all other aspects to new § 130.10, then the product is a food defined by new § 130.10 and must be labeled accordingly.

FDA notes that juices are defined in part by their Brix level or soluble solids content. The soluble solids of juices consist primarily of sugars. If any of the

sugars have been removed from a juice, the resulting product is a modified juice. As discussed in the final rule on percent juice labeling published elsewhere in this issue of the **Federal Register**, modified juices cannot use the percent juice labeling values in § 101.30 because of the reduced soluble solids content. The manufacturer would have to develop an alternate means of determining the percent juice in modified juice products.

9. Several comments stated that they considered the allowance of additional moisture in a modified cheese product to be necessary. One comment added that maximum moisture content requirements are as much barriers to lower fat versions of standardized products as minimum fat requirements.

Another comment added that other deviations from the standard, such as different levels of total solids or the use of modified processing conditions, are frequently required to meet the performance characteristics of the traditional standardized food and should be explicitly permitted in this regulation. It recommended that the last sentence of proposed § 130.10(a) be changed to read, "The food shall comply with paragraphs (b), (c), and (d) of this section." It further recommended that the following sentence be added at the beginning of proposed § 130.10(c):

Deviations from noningredient provisions of the standard of identity (such as moisture content, food solids content requirements, or processing conditions) are permitted in order that the substitute food possess performance characteristics similar to those of the standardized food.

FDA agrees that there are noningredient requirements mandated by some standards in parts 131 through 169 that could restrict manufacturers' ability to produce modified foods under new § 130.10. The agency recognizes that in some standardized foods, such as cheeses, the standard mandates a maximum moisture content, and that modified foods may not conform to this requirement and still retain the necessary performance characteristics to use the standardized name.

New § 130.10(a) states that the foods prescribed by this general definition and standard of identity are those foods that substitute for a standardized food but that do not comply with the standard because of a deviation that is described by a nutrient content claim. FDA noted in the proposal that the ingredients used in the modified version of the standardized food should be those ingredients provided for by the traditional standard with only those deviations necessary to attain an acceptable finished product that meets the requirements of the nutrient content claim that is used (56 FR 60512 at 60519). Thus, under new § 130.10(d)(1) the agency is providing for the addition of safe and suitable ingredients not normally found in the standardized food so that § 130.10 foods are not inferior in performance characteristics to the traditional standardized food. In like manner, FDA believes that the modified version of the standardized food should comply with the noningredient provisions of the traditional standard with only those noningredient deviations necessary to attain an acceptable finished product that meets the requirements of the nutrient content claim that is used.

For the above reasons, FDA has been persuaded by the comments that modifications to the regulation are needed to allow for deviations from the noningredient requirements of the standards. Therefore, the agency is adding a new sentence at the beginning of new § 130.10(c) which states:

Deviations from noningredient provisions of the standard of identity (e.g., moisture content, food solids content requirements, or processing conditions) are permitted in order that the substitute food possesses performance characteristics similar to those of the standardized food.

In addition, the agency is amending the last sentence of new § 130.10(a) to read: "The food shall comply with the relevant standard in all other respects, except as provided in paragraphs (b), (c), and (d) of this section." The agency believes that this action will: (1) Increase the manufacturers' ability to produce modified foods under new § 130.10, (2) provide consumers with a greater variety of such foods, and (3) assist consumers in maintaining healthy dietary practices. The agency notes, however, that this exception does not apply to processes that are important to public safety such as pasteurization. FDA concludes that this action will promote honesty and fair dealing in the interest of consumers.

10. One comment stated that the requirement of nutritional equivalency (new § 130.10(b)) for lower fat ice creams mitigates the need for lower fat ice creams to meet the 4.5 pounds per gallon requirement in the standard of identity for ice cream in § 135.110.

FDA agrees with the comment. FDA published an advance notice of proposed rulemaking (ANPRM) (Docket No. 88P–0251) in the **Federal Register** of January 22, 1991 (56 FR 2149) concerning the filing of several petitions to amend the standards for ice cream and ice milk and to establish standards for reduced fat, lowfat, and nonfat ice creams. The petitions requested that FDA establish a minimum weight of 4.0 pounds per gallon for the lower fat products.

A comment received in response to the ANPRM that opposed the reduction in weight stated that the change could be construed as intentionally deceiving the consumer. The comment stated that while there are economic and competitive advantages, there appears to be no other serious justification for such cheapening of the product.

However, most of the comments received in response to the ANPRM that addressed the minimum weight issue supported the proposed minimum requirement of 4.0 pounds per gallon. They stated that the processing and formulation changes that accompany the removal of fat in the manufacture of fat reduced ice cream products result in a less dense product. According to these comments, creaminess and product stability, which are lessened by fat removal, can be improved by increasing the amount of air incorporated into the product or by utilizing more precise control of the freezing process.

FDA concludes that it is reasonable to exempt modified ice cream products from the minimum weight requirement of 4.5 pounds per gallon, so that these products can achieve the performance characteristics (e.g., creaminess) of ice cream, as long as the product is not nutritionally inferior to ice cream. The agency concludes that this exemption will assist consumers in maintaining healthy dietary practices by providing for modified ice cream products that have performance characteristics that are similar to ice cream. This exemption is provided by the new sentence that is being added to the beginning of new § 130.10(c). However, FDA does not believe that fat reduced ice cream products should contain less than 4.0 pounds per gallon, as recommended by the petitioners of these ice cream products, because the desired effects can be achieved within this allowance, and the modified foods should resemble the traditional standardized foods as closely as possible.

The inclusion of air in § 130.10 foods (e.g., nonfat ice cream, light margarine, and reduced fat peanut butter) in excess of that which is reasonably required to achieve the performance characteristics of the standardized food for which it substitutes constitutes deception and will be deemed to adulterate the food under section 402(b) of the act in that excess air is substituting for a valuable constituent. Therefore, FDA is including in new § 130.10(c) a requirement that deviations from provisions of the standard must be the minimum necessary to achieve this effect, or the

food will be deemed to be adulterated under section 402(b) of the act. FDA believes that this requirement will promote honesty and fair dealing in the interest of consumers.

Serving size issues relating to "aerated" products (i.e., products that include added air) that are sold by weight are addressed elsewhere in this issue of the **Federal Register** in a document entitled "Food Labeling: Serving Sizes."

C. Nutrient Content Claims

11. Several comments stated that the use of nutrient content claims such as "lowfat," "lite," and "reduced" should not be allowed on the label of standardized foods because they are confusing, even if they are defined.

Other comments expressed concerns about the required labeling, arguing that it is excessive. One comment urged FDA not to include too many restrictions on the wording or use of nutrient content claims because such restrictions would only befuddle the consumer and defeat the purpose of the claims.

FDA is establishing definitions for a number of nutrient content claims in the nutrient content claims final rule. In defining these terms, FDA has carefully considered each nutrient content claim to ensure that it will be meaningful to consumers. The definitions for the claims and § 101.13 prescribe the specific labeling that must accompany the claim. As consumers learn what a claim means, they will be able to understand that a product such as "light margarine" has been modified in a way that has reduced its fat content. Thus consumers will be able to easily identify the food and will be able to find out more about the food through information on the label. Therefore, FDA concludes that no action is necessary in response to these comments.

12. One comment stated that only expressed nutrient content claims should be used with the names of standardized foods. It stated that implied nutrient content claims such as "light" or "healthy" should not be used in this manner (e.g., "healthy ice cream").

The agency agrees with the comment. However, the term "light" is not an implied claim and is being defined as an expressed nutrient content claim as discussed in the nutrient content claims final rule. In § 101.13(b)(1), FDA defines an "expressed nutrient content claim" as any direct statement about the level (or range) of a nutrient in the food, e.g., "low sodium." An "implied nutrient content claim" is defined in § 101.13(b)(2) as any claim that describes the food or an ingredient therein in such a manner that suggests that a nutrient is absent or present in a certain amount (e.g., "high in oat bran"), or that suggests that the food, because of its nutrient content, may be useful in maintaining healthy dietary practices and is made in association with an explicit claim or statement about a nutrient (e.g., "healthy, contains 3 g of fat").

Because the name of a new modified food distinguishes it from the standardized food, the claim must be expressed for consumers to understand how the new modified food differs from the traditional food. Therefore, FDA concludes that only expressed nutrient content claims may be used in the name of the food under new § 130.10. Implied claims may be used as provided in § 101.13(b)(2) but not in conjunction with the name of the § 130.10 food. Therefore, the agency is modifying new § 130.10(a) and (e) to state that the nutrient content claim must be an expressed claim. FDA believes that this revision will promote honesty and fair dealing in the interest of consumers.

D. Nutritional Inferiority

13. One comment stated that in determining nutritional inferiority, there is no clear indication of the nutrients and levels thereof that a § 130.10 food is expected to match. It stated that some specifications should be made, or provisions should be included, for developing nutrient data bases for those standardized foods that § 130.10 foods with nutrient content claims must match to avoid "nutritional inferiority."

FDA disagrees with the comment. New § 130.10 sets forth general requirements for foods named by use of an expressed nutrient content claim and a standardized term. Under new § 130.10(b), the modified product must not be nutritionally inferior, as defined in § 101.3(e)(4), to the standardized food. FDA believes that this general requirement is adequate because § 101.3(e)(4) sets very specific requirements defining nutritional inferiority. The agency concludes that new § 130.10 should not specify required amounts of essential nutrients that must be added to a modified food, and that no change is necessary in new § 130.10.

The agency adds that nutrient values for the traditional standardized product can be found in a current valid composite data base.

14. One comment agreed that § 130.10 foods should not be nutritionally inferior to the traditional standardized food. However, it stated that inferiority in any single nutrient should be defined as a "significant" reduction, that is, a reduction of 10 percent or more of the Reference Daily Intake/Daily Reference Value (RDI/DRV) of a nutrient that is present in a "measurable amount." In addition, the comment stated that nutritional inferiority of the product itself should not be based on inferiority in a single nutrient. It stated that in such cases, the unavoidable reduction of one nutrient could be compensated by meaningful additions or improvements in one or more other nutrients. For example, the comment stated, there are some foods for which it is difficult or impossible to reduce the amount of a component such as fat without also reducing the amount of a nutrient such as protein. It stated that the reduction in protein could be balanced by additions of vitamin A and riboflavin.

FDA disagrees with this comment. According to § 101.3(e), a food that is nutritionally inferior to another food is an imitation of that food and must be labeled as such. Section 101.3(e)(4)(i) defines nutritional inferiority as any reduction in the content of an essential nutrient that is present in a measurable amount (excluding fat or calories). Section 101.3(e)(4)(ii) defines a measurable amount of an essential nutrient in a food as 2 percent or more of the DRV of protein or the RDI of any vitamin or mineral listed under § 101.9(c)(7)(iv). The agency considers a measurable amount to be a significant amount for this purpose. All nutrients that are considered in determining the status of a food under § 101.3(e)(4) are important, and the agency does not believe that the addition of one nutrient could compensate for another. Therefore, FDA concludes that foods that have significantly less protein or other essential nutrients than a standardized food are not modified versions of the standardized food, do not comply with the requirements of this regulation, and must be labeled as "imitation."

15. One comment stated that the agency should reconsider the requirement that any modified food, identified as a "light," "reduced," or "lowfat" version of a standardized food, in which there is a nutrient reduction be fortified in order not to be called "imitation." The comment stated that such nutrient addition was not necessary because the comparative nutrition label will clearly identify the nutritional differences between these two different foods.

The agency disagrees with the comment. Although FDA agrees that the nutritional differences between these products would be apparent from the nutrition information, foods that are

nutritionally inferior to the standardized food must be labeled as "imitation" under section 403(c) of the act. New § 130.10 does not include imitation foods.

16. One comment requested that the agency clarify that when the modified food substitutes for more than one standardized food, the modified food should be deemed in compliance with proposed § 130.10 if it is nutritionally equivalent to any of the several standardized foods. The comment stated that cottage cheese (21 CFR 133.128) and lowfat cottage cheese (21 CFR 133.131) may vary in vitamin A content based on their different fat levels. Thus, the comment stated, a nonfat cottage cheese should be considered nutritionally equivalent under new § 130.10 if its vitamin A content is equivalent to that required by either food standard because it clearly is a modified version of either food.

FDA disagrees with this comment. The agency recognizes that a nonfat cottage cheese product could be compared to cottage cheese (§ 133.128), dry curd cottage cheese (§ 133.129) or one of the lowfat cottage cheese products (§ 133.131). The agency acknowledges that target levels for nutrients necessary to determine nutritional equivalency of a food will depend on whether the food is compared to one food or another. However, the § 130.10 food must not be nutritionally inferior to the standardized food whose name is used in the name of the food. FDA concludes that because the reference food in the name "nonfat cottage cheese" is "cottage cheese," it would be misleading to consumers to make the comparison of nutritional equivalency to any other cottage cheese product.

E. Performance Characteristics

In the proposal for this final rule, FDA requested comments concerning: (1) The requirement that the performance characteristics of the new product be similar to those of the standardized food, (2) the performance properties that are of greatest importance to consumers, and (3) what differences in performance characteristics a modified standardized product should be able to have and still be considered to resemble the standardized food closely enough to be included in that product category (56 FR 60512 at 60519 and 60521).

17. Several comments stated that it would be acceptable to a consumer that wants lower fat foods to have products with fat replacers resemble the original products as closely as possible, especially with respect to texture, taste, and nutrition. One comment urged FDA to set high standards for performance requirements for § 130.10 foods. It stated that without appropriately high standards, consumers may be misled by the use of familiar names, and that, ultimately, the value of the standards themselves will be diluted.

Two comments suggested that, in order to use the name of the standardized product with a nutrient content claim, the product must perform at least one of the principal functions of the standardized product substantially as well as the standardized product. Consumers can then choose to purchase the modified product instead of the standardized product for use in that function. One comment added that a reduced fat cheese must at a minimum be suitable for eating directly from the package or for melting and cooking. It stated that the product need not serve both purposes, so long as the performance deficiencies are clearly and prominently labeled on the front of the package.

The agency agrees that the § 130.10 food should resemble the standardized food in as many ways as possible. FDA also agrees that at a minimum, a modified food must perform at least one of the principal functions of the standardized product as well as the standardized food. FDA believes that consumers should be able to count on using a modified food in the same manner that they use the traditional standardized food in, at the very least, one of the principal functions as the standardized food. To achieve this objective, FDA is requiring in new § 130.10(c) that modified standardized foods must resemble the standardized foods, and that differences in the performance characteristics must be clearly stated on the principal display panel of the label. In addition, the agency is adding a statement to new § 130.10(c) to require that "the modified product must perform at least one of the principal functions of the standardized product substantially as well as the standardized product." FDA believes that this action is necessary to ensure the minimum necessary similarity between the modified and traditional products and, thus, will promote honesty and fair dealing in the interest of consumers.

18. One comment questioned what methods the agency would use to measure significant differences in product quality and to monitor critical performance characteristics.

FDA expects that modified versions of standardized foods will perform in a manner that is generally acceptable to the public. New § 130.10 requires that the performance characteristics of the food be similar to those characteristics of its standardized counterpart unless the differences between the two foods are explicitly stated on the label. In addition, the § 130.10 food must perform at least one of the principal functions of the standardized food substantially as well as the standardized product. Although it was not the agency's intent to develop specific performance standards for each product, FDA plans to examine the performance characteristics and product quality of these modified versions of standardized foods, as it would for other types of food products, through scientific reviews or experimental investigations. In addition, FDA will use all avenues available to the agency (e.g., sample analysis, inspections, surveys, and followup investigations of consumer and trade complaints) to identify products that do not comply with the new regulation and will enforce this regulation as the need arises.

F. Labeling of Performance Characteristics

19. Several comments objected to the requirement in proposed § 130.10(c) that if there is a significant difference in performance characteristics between the food under proposed § 130.10 and the standardized food, the label must include a statement informing the consumer of such difference. One comment stated that some performance characteristics (e.g., flavor or texture) tend to be more subjective, and that if a flavor comparison is not favorable, manufacturers would not be inclined to call attention to such a difference. It stated that it would be a disincentive to food manufacturers to reduce the fat content in food. Another comment stated that a regulation to require a label statement pointing out differences in performance is not necessary unless health or safety is involved. One comment stated that the most specificity FDA should include in this regulation regarding performance characteristics is a reference to substantial equivalence in organoleptic and nutritional qualities.

One comment stated that manufacturers would find it advisable, for marketing reasons, to inform the consumer how a modified version of a standardized food performs differently than the standardized product. One comment supporting the label statements noted that bread spreads currently on the market are erratic about stating whether they can be used for cooking, and that consumers are confused as a result. Other comments expressed concern about diluting the value of the standards if consumers are

misled by the use of familiar names on modified products.

Under sections 201(n) (21 U.S.C. 321(n)) and 403(a) of the act, the label or labeling of the food must disclose to consumers what they are buying when they purchase these modified foods. Information disclosing differences in performance characteristics (e.g., physical properties, flavor characteristics, functional properties, and shelf life) is a material fact under section 201(n) of the act because it bears on the consequence of the use of the article. Accordingly, this information must be communicated to the consumer on the product label, or the labeling would be misleading, and the product would be misbranded under section 403(a) of the act.

Therefore, a provision in new § 130.10(c) that requires disclosure of differences in performance characteristics between the modified food and the traditional standardized food is fully consistent with the act.

FDA is providing for noningredient deviations in new § 130.10(c) (e.g., moisture content) and for the use of safe and suitable ingredients for certain specified purposes in new § 130.10(d)(1) (e.g., to add flavor) in order that the modified food may possess similar performance characteristics as the traditional standardized food. FDA believes that these provisions in new § 130.10 provide manufacturers ample latitude in producing modified products.

20. Two comments recommended that the label statement be mandatory only for differences in performance characteristics that materially limit the uses of the modified food compared to the traditional standardized food that it resembles. One comment stated that market forces will encourage manufacturers to inform consumers about positive differences, and that consumers who select a product for its reformulated nutrient content will not be misled if they are not told about a positive change that the manufacturer believes is not sufficiently important to highlight on the product label. The comment noted that FDA would not object if the label did not alert consumers to a minor improvement in a performance characteristic that consumers consider to be relatively unimportant for that food, such as the freezing point of eggnog. In addition, the comment stated, a product may have several differences in performance characteristics, and several label statements could be confusing to consumers. The comment recommended that FDA modify new § 130.10(c) by limiting the labeling requirement to adverse changes that materially affect the use of the product.

The agency has been persuaded by these comments. FDA agrees that there are differences in performance characteristics that consumers may not deem to be important, such as the freezing point of eggnog. Consumers commonly store eggnog at refrigerator temperatures, and, therefore, the freezing point of this product is not of material interest to consumers. In addition, FDA believes that unnecessary label statements may be confusing to consumers and may detract from other important information on the label.

Therefore, the agency is revising new § 130.10(c) to state that:

> * * * if there is a significant difference in performance characteristics that materially limits the uses of the food compared to the uses of the standardized food, the label shall include a statement informing the consumer of such difference (e.g., if appropriate, "not recommended for cooking").

21. Comments also suggested that FDA affirm in the final rule that statements of differences in performance characteristics can be presented as recommendations for use.

FDA agrees with the comments suggesting that differences in performance characteristics may be presented as recommendations for use. For example, a reduced fat margarine may not perform the same as margarine for use in frying. A statement such as "not recommended for frying purposes" or as "recommended for use only as a spread" would be acceptable to advise consumers of the difference in performance characteristics.

22. Comments also asked whether shelf life could be presented as a date by which the product should be used.

The agency agrees that a date by which a product should be used is an appropriate manner to express differences in shelf life.

23. Several comments objected to the requirement in proposed § 130.10(c) that label statements concerning differences in performance characteristics must appear on the principal display panel within the bottom 30 percent of the area of the label panel with appropriate prominence, in type that shall be no less than one-half the size of the type used in such claim but no smaller than one-sixteenth of an inch. One comment noted a conflict with proposed § 101.13(d)(1) with regard to location of this information on the label. Some comments addressed concerns about label clutter on the principal display panel and stated that these concerns are enhanced by the proposed requirement that the bottom 30 percent of the principal display panel contain a statement of any differences in performance characteristics between the § 130.10 food and the standardized food. Comments urged FDA to allow the statements to appear on any panel of the food product. One comment added that a simple requirement of proximity and appropriate prominence should be more than adequate to prevent consumer confusion. One comment stated that the proposed requirements are excessive and fail to meet the requirements of the President's directive that regulation should rely on market mechanisms to the maximum extent possible. It stated that consumers who buy nutritionally modified versions of familiar foods and are disappointed with their performance, because they did not know in advance what to expect, simply will not buy again, and the products will quickly fail. It added that FDA does not need to regulate this guaranteed result. Some comments stated that they did not believe it necessary to prescribe a minimum type size for this disclosure statement, but that the statement should appear on the principal display panel in a clear and conspicuous fashion.

The agency disagrees with these comments. Different brands of a particular modified food may have different performance characteristics depending on the manufacturing technology used in making the § 130.10 food. For example, reduced fat cheddar cheese made by one manufacturer may be suitable only for melting and cooking, while another brand may be suitable only for eating directly from the package as a snack. Therefore, consumers must be informed about the characteristics of a food to make judgments concerning the use of a product before purchase. The necessary information must appear on the same part of the label as the name of the § 130.10 food (i.e., the principal display panel) so that consumers can make informed choices. Moreover, this regulation is consistent with the President's directive because it is providing increased flexibility to the market in that it provides that qualifying versions of standardized foods may be sold under names that consumers recognize.

Under section 403(f) of the act, FDA believes that the statement informing consumers of differences in performance characteristics must appear on the label with such conspicuousness and in such terms as to render it likely to be read and understood by the consumer under customary conditions of purchase and use. The agency concludes that the statement must appear in the same area of the label as the statement of identity for the

modified product so that consumers will know where to find such information. Moreover, because the statement is a material fact that helps to describe the differences between the modified food and the traditional food, it must appear in close proximity to the statement of identity. See, e.g., *United States* v. *An Article of Food * * * "Manischewitz * * * Diet Thins,"* 377 F. Supp. 746, 749 (E.D. N.Y. 1974).

FDA recognizes that it inadvertently proposed in § 130.10 to require statements informing consumers of differences in performance characteristics to appear in possibly two separate locations on the label. The agency acknowledges that one statement is sufficient to inform consumers. To be consistent with the labeling of other foods, the agency concludes that the statement concerning differences in performance characteristics must appear on the label in compliance with the requirements of § 101.13(d)(1). Thus, the agency has modified new § 130.10(c) to state that the statement explaining differences in performance characteristics must appear on the label in compliance with the requirements of § 101.13(d).

G. Ingredients

1. Ingredients Provided for By the Regulation

24. Two comments objected to FDA restricting the major ingredients used in § 130.10 foods to those specified in the standard. One comment stated that this provision would not empower consumers to select a healthy diet but would restrict the number of apparent "healthy" choices available by requiring products made with alternate ingredients to bear unappealing names. It also stated that this provision would not provide an incentive to manufacturers to develop nutritionally improved foods but would restrict their ability to develop such products by unnecessarily limiting the technology available.

The agency disagrees with these comments. The agency believes that foods named by use of a nutrient content claim and a standardized term must resemble the standardized food in as many ways as possible, or the use of the standardized term would be misleading to consumers. Therefore, FDA concludes that the ingredients used in the modified version of the standardized food should be those ingredients provided for by the traditional standard, with only those deviations necessary to attain an acceptable finished product that meets the requirements of the nutrient content claim that is used and new § 130.10.

2. Safe and Suitable Ingredients

25. Several comments stated that proposed § 130.10(d) should provide for the use of safe and suitable ingredients generally in accordance with current good manufacturing practices rather than limiting them to specific functions. One comment stated that the language in proposed § 130.10(d) concerning ingredient substitutions should be broadened to encompass all of the product characteristics embraced by proposed § 130.10(c) and by the definition of "substitute" in § 101.13(d). Another comment added that safe and suitable ingredients should be allowed for purposes of improving appearance as well as the other characteristics mentioned in the proposal.

FDA disagrees that the use of safe and suitable ingredients should be extended for all purposes. The agency believes that § 130.10 foods should deviate from the standard of identity only when necessary to achieve the functions of ingredients or components of ingredients that are no longer present in the mandated quantities. As required in new § 130.10(c), the performance characteristics (e.g., physical properties, flavor characteristics, functional properties, and shelf life) of the modified food must be similar to those of the traditional standardized food. FDA believes that the use of safe and suitable ingredients added as necessary to improve texture, add flavor, prevent syneresis, and extend shelf life adequately compensates for any deficiencies in performance characteristics. As discussed previously, § 130.10 foods do not include all substitute foods. Therefore, FDA does not believe that new § 130.10(d) should be broadened to encompass all types of substitute foods.

However, FDA concedes that the use of safe and suitable ingredients to improve the appearance of a product has merit. For example, modified foods with significantly less fat may appear more translucent than the standardized food. Thus, such ingredients are necessary to ensure that the product is not inferior in performance characteristics. Therefore, FDA is amending new § 130.10(d)(1) to provide that safe and suitable ingredients may be added to improve the appearance of a modified food named by use of a nutrient content claim and a standardized term.

26. One comment stated that it believes that to "add flavor" includes sweetness and requested that FDA confirm this interpretation by including a parenthetical "(including sweetness)" following "add flavor" in proposed § 130.10(d)(1).

FDA disagrees with the premise of this comment. In § 170.3(o)(12), FDA defines "flavoring agents and adjuvants" as substances added to impart or help impart a taste or aroma in food. FDA defines nonnutritive and nutritive sweeteners separately from flavoring agents in § 170.3(o)(19) and (o)(21). In addition, labeling requirements for flavors differ significantly from those for sweeteners.

However, FDA does agree that the use of safe and suitable sweeteners to add sweetness should be provided for in new § 130.10 for modified foods. Many standards of identity provide only for the use of safe and suitable nutritive sweeteners or nutritive carbohydrate sweeteners (e.g., sour cream (§ 131.160), eggnog (§ 131.170), and margarine (§ 166.110)). Nonnutritive sweeteners could be effectively used to add the sweetness, but not the calories, that would otherwise be contributed by nutritive sweeteners in the traditional standardized food. Therefore, FDA believes that the use of safe and suitable sweeteners to add sweetness would assist consumers in maintaining healthy dietary practices. Thus, the agency is revising new § 130.10(d)(1) to provide that safe and suitable ingredients may be added to add sweetness to a modified food named by use of a nutrient content claim and a standardized term. When a sweetener that meets the "safe and suitable" definition in new § 130.3(d) is used in the formulation of a modified food for the purpose of adding sweetness to that food, the sweetener must be declared on the food label in accordance with all applicable regulations. FDA believes that this action will promote honesty and fair dealing in the interest of consumers.

27. One comment questioned whether the provision for the use of "safe and suitable" ingredients in § 130.10 foods would promote long-term product development, even though short-term product innovation may benefit from this policy. This comment further contended that allowing these foods into the marketplace would: (1) Erode the market share of traditional standardized foods, (2) harm the integrity of traditional standardized foods, and (3) lead to consumer confusion by blurring the differences between these standardized foods and their modified counterparts.

FDA disagrees with this comment. The agency believes that providing for the use of "safe and suitable" ingredients to improve texture, add flavor, prevent syneresis, extend shelf

life, improve appearance, or add sweetness in modified versions of standardized foods should not stifle long-term product development, nor should the introduction of these foods into the marketplace be damaging to the food industry on the whole.

On the contrary, standards of identity have been criticized as being too strict and confining, and because they limit food companies from achieving true product innovations. For instance, the dairy industry purportedly has been harmed because many of the products that dairy processing companies manufacture are subject to rigid standards of identity that require specific fat content. As a result, these firms have not been able to create new dairy food products that respond to consumer needs and demands for products that are reduced in fat and in calories.

FDA anticipates that there will be shifts in dietary consumption patterns from traditional foods that are higher in calories or in fat to modified forms of these foods that are reformulated to be lower in calories or in fat. However, this pattern of increased consumption of modified forms of traditional foods should help consumers to achieve recommended nutritional goals and should have a beneficial impact on the public health. In addition, FDA believes that the development, production, sale, and consumption of these reformulated foods will contribute to overall industry growth. Although the agency acknowledges that there is the potential that sales of certain standardized foods may remain stagnant or may even decline, these changing patterns in consumers' food purchasing habits in relation to recommended nutritional goals should create new opportunities for innovative food processors to develop a virtually limitless array of new products that will ultimately lead to an overall increase in sales and an expansion into new markets.

Regarding consumer confusion about the differences between a traditional standardized food and a modified form of such food bearing one or more nutrient content claims on its label, the agency believes that the use of carefully defined nutrient content claims as a part of the statement of identity on the label will enable purchasers of the modified versions of standardized foods to distinguish these foods from their standardized counterparts. New § 130.10 provides for proper labeling of these foods and the listing of all ingredients in the ingredient statement. Adequate product labeling, including defined nutrient content claims, accompanying label statements, and nutrition labeling, will enable consumers to distinguish traditional foods from modified versions of these foods, thereby contributing to improved consumer understanding of the characteristics of the products that they are purchasing.

28. One comment inquired whether specific caseinates would meet the "safe and suitable" definition and be permissible for use in § 130.10 foods.

FDA advises that the "safe and suitable" definition in new § 130.3(d) would permit the use of caseinates in foods subject to new § 130.10 provided that the standard of identity for the traditional food in question provides for such use. For example, the standard of identity for ice cream in § 135.110 permits the optional addition of one or more of the caseinates listed in § 135.110(c) in an ice cream mix containing not less than 20 percent total milk solids. Caseinates may be added to ice milk (§ 135.120) when the content of total milk solids is not less than 11 percent. FDA believes that it is reasonable to permit the use of such caseinates in modified versions of ice cream, provided that the product contains equivalent levels of nonfat milk solids to those contained in a 10 percent milkfat ice cream. That is, the modified product must contain at least 10 percent nonfat milk solids, and caseinates could be added after this minimum nonfat milk solids requirement has been met. FDA believes that modified ice cream, regardless of the milkfat content, should contain at least 10 percent of nonfat milk solids to ensure that the § 130.10 ice cream is not nutritionally inferior to ice cream with respect to calcium and protein. The addition of caseinates to replace the milk solids content constitutes deception and will be deemed to adulterate the food under section 402(b) of the act (21 U.S.C. 342(b)) in that caseinates are substituting for a valuable constituent.

On the other hand, the standards of identity for cheeses and related cheese products in part 133 (21 CFR part 133) do not provide for the use of caseinates. Therefore, under new § 130.10(d)(1) manufacturers may not use this class of ingredients in modified versions of cheese products as replacements for the optional dairy ingredients listed in the standards of identity in part 133. However, use of small amounts of safe and suitable caseinates may be used for the reasons listed in new § 130.10(d)(1) (e.g., to improve texture) in modified versions of standardized foods as appropriate.

Any caseinates used in a § 130.10 food must be declared in the ingredient statement according to new § 130.10(f), including identification with an asterisk if the use of caseinates is not provided for by the traditional standard.

3. Addition of Water and High Moisture Ingredients

In the proposal, FDA requested comment from interested persons concerning the appropriateness of the addition of high moisture ingredients and water to foods as ingredients to replace fat and calories in modified products (56 FR 60512 at 60520).

29. A number of comments requested that FDA provide for the addition of water. Two comments stated that the addition of water is critical to the manufacture of modified standardized products such as modified salad dressing and mayonnaise. One comment added that the emulsifying properties of certain gums are activated only by the addition of water. Several comments stated that it is appropriate to allow for the addition of water as long as it is appropriately labeled. Conversely, two comments requested that FDA not permit the addition of water to a food subject to proposed § 130.10.

A number of comments stated that the addition of high moisture ingredients to foods subject to proposed § 130.10 is appropriate. One comment noted that moisture content variability may occur because of water contributed by safe and suitable ingredients that are components of such foods. It added that provision should be made to require that such moisture differentials are accurately and adequately reflected on the label of foods subject to new § 130.10. Another comment stated that where, with current technology, the production of reduced fat products is not possible without the addition of high moisture ingredients, their addition should be permitted.

One comment stated that most current fat reduction technologies require the addition of high moisture ingredients and water. It recommended that FDA allow high moisture ingredients and water to replace fat in § 130.10 products, and that FDA use performance standards rather than deviations from a "recipe" to protect consumers. Another comment recommended that FDA allow the use of high moisture ingredients and water to the level necessary to replace fat and calories, as long as the modified food is not nutritionally inferior to the traditional food.

FDA agrees that the addition of water may be necessary for the hydration of some ingredients that would be permitted under the safe and suitable ingredient provision. In addition, FDA notes that there is consumer demand to

purchase products that have a significant reduction in fat and calories. Water is an ingredient that could effectively accomplish this purpose when used to replace fat and calories in modified products. Therefore, the agency is adding new § 130.10(d)(5) to provide for the addition of water as an ingredient to replace fat and calories in modified products. FDA believes that such addition of water will assist consumers in maintaining healthy dietary practices by providing for an ingredient that will allow manufacturers to produce a greater variety of modified versions of traditional standardized foods. Moreover, the consumer is protected against the possibility of excess water being added by new § 130.10(c), which states that deviations from the ingredient and noningredient provisions of the traditional standard must be the minimum necessary to qualify for the nutrient content claim while maintaining similar performance characteristics as the standardized food, or the food will be adulterated under section 402(b) of the act.

FDA also agrees that the use of high moisture ingredients is necessary to reduce calories and fat in some foods. Comments did not mention any specific high moisture ingredients that the regulation should include. Therefore, all high moisture ingredients used in a § 130.10 food must either be ingredients that are provided for by the respective standard of identity or provided for by the safe and suitable ingredient provision of new § 130.10(d)(1).

The agency notes that some foods subject to new § 130.10 may need to exceed the moisture requirements of the respective standards of identity to make a nutrient content claim. For example, the standard of identity for cheddar cheese (§ 133.113) stipulates a maximum moisture content of 39 percent by weight and a minimum milkfat content of 50 percent by weight of the solids. Under new § 130.10(c), a reduced fat cheddar cheese may exceed the maximum moisture level stipulated by § 133.113 concurrent with the 50-percent reduction in the fat content, but it still must not be nutritionally inferior. The increase in moisture content occurs because less whey is drained from the product during processing. The high moisture ingredients would, therefore, be the same dairy ingredients (i.e., milk, nonfat milk, or cream) provided for by the traditional standard.

The addition of water and high moisture ingredients must be declared in the ingredient statement as required in new § 130.10(f). Because new § 130.10(b) requires that the modified food must not be nutritionally inferior to the standardized food, a modified food that contains significantly less calcium or any other nutrient than the standardized food because of the use of water or a high moisture ingredient must be labeled as an imitation. FDA believes that moisture differentials will be adequately reflected on the label through order of predominance ingredient labeling and labeling of any differences in performance characteristics (e.g., shorter shelf life because of increased moisture content).

4. Flavors

30. Two comments urged FDA to exempt from the labeling requirement of § 101.22(i) those flavors added solely at the level necessary to replace flavors lost by reformulation of the food. The comments also said that there was no reason to exempt any flavor added in amounts greater than necessary to maintain the flavor of the traditional food.

FDA disagrees that there is a need to exempt flavors added to replace flavors lost by reformulation of the food from the requirements of § 101.22(i). Section 101.22(i) only refers to the labeling of characterizing flavors. Natural and artificial flavors that do not characterize a food need only be declared in the ingredient statement. However, FDA believes that consumers should be informed from information on the principal display panel when artificial characterizing flavors have been added to a food.

In the **Federal Register** of January 19, 1973 (38 FR 2139), FDA proposed a uniform labeling policy for flavor designation that was patterned, with appropriate modification, after the ice cream standard of identity in § 20.1 (21 CFR 20.1) (current § 135.110 (21 CFR 135.110)). According to the standard, ice cream may or may not be characterized by the addition of flavoring ingredients. The existing standard in 1973 listed the optional characterizing ingredients (§ 20.1(b)) that could be used in ice cream. These characterizing ingredients, not the individual flavors contributed by the milk, cream, and other optional ingredients, were the flavors subject to the labeling provisions.

Therefore, the flavors that are lost by reformulation are likely not to be those that characterize the food but those that are an inherent part of the basic required ingredients that are no longer present in the reformulated food. Thus, they need only be declared in the ingredient statement as natural or artificial flavors, as appropriate. For example, natural and artificial eggnog flavor components may be added to light eggnog to add flavor. These flavor components must be included in the declaration of ingredients but need not appear anywhere else on the label. However, if a natural and artificial eggnog flavor that comprises the total eggnog flavor profile is added to a light eggnog, it is a characterizing flavor and must be labeled according to § 101.22(i). If any portion of the characterizing flavor is artificial, it must be labeled as artificial flavor under § 101.22(i).

31. A comment objected to FDA's choice of "light margarine" as an example of a § 130.10 food using a standardized name. According to the comment, this example implied that the label of a food with the name "light margarine" would have to comply with the flavor labeling regulations of § 101.22 if artificial butter flavor were used in the food for flavoring purposes.

According to § 166.110(b)(7) (21 CFR 166.110(b)(7)) on flavoring substances in margarine, "if the flavoring ingredients impart to the food a flavor *other* than in semblance of butter, the characterizing flavor shall be declared as part of the name of the food in accordance with § 101.22 of this chapter" (emphasis added). Flavoring ingredients that impart the flavor of butter to margarine thus may be added to the food without declaring such flavor as part of the name of the food.

Because the intent in producing "light margarine" is to modify the fat and calorie content and not the flavor, the agency believes that it is reasonable to treat the declaration of flavoring ingredients on the label of "light margarine" in a like manner to their declaration on the label of margarine that complies with the standard of identity in § 166.110. The use of an artificial butter flavor in the formulation of a "light margarine" would not, therefore, necessitate the naming of this food as "light margarine, artificially flavored" as the preamble to the November 27, 1991, proposal (56 FR 60512 at 60519) stated. The agency reiterates, however, that natural and artificial flavors other than those in semblance of butter in "light margarine" must be declared in the ingredient statement in accordance with the applicable sections of part 101.

5. Fat Analogs

In the proposal, FDA stated that it is aware of the recent development of fat analogs and requested comments from interested persons concerning the appropriateness of the use of approved fat analogs to replace the fat in foods subject to proposed § 130.10 (56 FR 60512 at 60520).

32. A number of comments stated that it would be appropriate to allow for the

addition of fat analogs in modified versions of standardized foods that are subject to proposed § 130.10. One comment recommended that FDA not impose any unique requirements on the use of fat analogs as replacements for fat and calories. Several comments stated that the addition of fat analogs would be appropriate as long as the food is properly labeled. One comment urged the use of a prominent disclosure statement of ingredients such as fat analogs on the principal display panel.

One comment stated that the use of approved fat analogs should be permitted in proposed § 130.10 foods only: (1) Where a particular analog is appropriate for the type of food in view of the composition of the standardized food (e.g., dairy fat analogs for dairy products), and (2) use of an analog is necessary to achieve a substantial reduction in fat. The comment stated that limiting the uses of analogs to those appropriate for a particular product category would serve the consumer interest in limiting deviations from standardized products to those really necessary to achieve reductions of fat.

Another comment stated that without the ability to use fat analogs, food manufacturers may find it difficult or impossible to accomplish the desired reductions in fat while maintaining product performance. It urged FDA to provide for the use of these ingredients in proposed § 130.10, rather than requiring a much more cumbersome regulatory process in the future. It stated that a statement should be added to proposed § 130.10(d) to the effect that fat substitutes that are approved for use in the food may replace the milkfat or other fat required by the standard.

Several comments stated that no addition of fat analogs should be allowed for a food subject to proposed § 130.10. One comment was concerned that the use of fat analogs would significantly alter the identity of the food and, therefore, the food would no longer resemble the traditional food. Other comments stated that fat analogs should not replace ingredients that would provide more healthful nutrients in modified foods.

FDA believes that there may be some instances where the use of fat analogs is appropriate and may be necessary to reduce the fat and calories while maintaining the performance characteristics of a food. The use of fat analogs will allow manufacturers to produce a variety of modified foods with greater reductions in fat and with the same performance characteristics as the traditional food. Thus, consumers will benefit by having a greater variety of modified foods available.

However, under § 130.10(d)(1), the fat analog used in § 130.10 foods must be safe and suitable as defined in new § 130.3(d). Moreover, under § 130.10(c), the amount used must be the minimum necessary to achieve similar performance characteristics as with the fat they replace, and under § 130.10(c). In addition, FDA agrees with the comment that stated that the fat analog must be appropriate for use in the particular type of food. New § 130.10(d)(2) states that an ingredient or component of an ingredient that is specifically required by the standard must not be replaced or exchanged with a similar ingredient from another source unless the traditional standard provides for the addition of such ingredient. The § 130.10 food must resemble the traditional standardized food. Thus, the major ingredients of a category of products should be from that variety of food (e.g., the major ingredients in dairy products should be dairy ingredients), and some ingredients are not appropriate to add to some modified foods that use the traditional standardized name. For example, under new § 130.10(d)(2), vegetable oil is not an appropriate ingredient to replace the milkfat in dairy products, or the fat in egg products, if the food is to use the standardized name as provided for in new § 130.10. Similarly, a fat analog from a vegetable or egg source is not an appropriate ingredient to replace the milkfat in dairy products using the standardized terms unless the dairy product provides for the use of egg or vegetable ingredients.

Therefore, FDA is adding a provision to new § 130.10(d)(5) to permit the use of safe and suitable fat analogs in accordance with new § 130.10(c), (d)(1), and (d)(2) in modified versions of the standardized food. The addition of fat analogs must be declared in the ingredient statement as required in new § 130.10(f). Because new § 130.10(b) requires that the modified food must not be nutritionally inferior to the standardized food, a modified food that contains significantly less of any nutrient than the standardized food because of the use of fat analogs must be labeled as an imitation. FDA believes that any use of fat analogs would be adequately reflected on the label through order of predominance ingredient labeling.

6. Use of Similar Ingredients

33. One comment suggested that the requirement that ingredients "specifically required" in new § 130.10(d)(2) either needs to be defined or its relationship to "mandatory" and "characterizing" ingredients needs to be explained by FDA. The comment said it assumed that it was FDA's intent in the proposed rule to not allow substitution for ingredients with similar ingredients that are deemed to be mandatory by the standard. FDA agrees with this comment. Ingredients that are specifically required by the standard are mandatory ingredients in standardized foods. Characterizing ingredients may be as optional ingredients under some standards (e.g., ice cream (§ 135.110)) and in those cases are not mandatory. The provision in new § 130.10(d)(2) prohibits the replacement or exchange of ingredients specifically required or mandated by the traditional standard with functionally similar ingredients from other sources that are not provided for by the traditional standard.

34. One comment stated that only dairy products should be used to replace milkfat in dairy products.

FDA agrees that dairy ingredients should be used to replace milkfat in dairy products. However, FDA acknowledges that other ingredients may be needed in small amounts to replace all of the functions of the milkfat that has been removed. A safe and suitable ingredient may be added to improve texture, prevent syneresis, add flavor, extend shelf life, improve appearance, or add sweetness under new § 130.10(d)(1), so long as it meets the requirements of the other parts of new § 130.10(d) and the label of the food complies with new § 130.10(f)(2). FDA adds that as stated previously, any fat analog used in dairy products must be from a dairy source.

35. One comment stated that proposed § 130.10(d)(2) is unnecessary and has the potential to be misinterpreted as, for example, prohibiting the use of a synthetic fat replacer to replace milkfat.

FDA disagrees that proposed § 130.10(d)(2) is unnecessary. Some ingredients are not appropriate to add to some modified foods that use the standardized name. In new § 130.10(d)(5), FDA is specifically providing for the use of safe and suitable fat analogs in new § 130.10 foods to replace fat and calories. However, some fat analogs are not appropriate for a particular type of food and are prohibited from use in a modified food by new § 130.10(d)(2). For example, the standard for sour cream (§ 131.160) states that sour cream contains not less than 18 percent milkfat. FDA believes that replacing the milkfat in sour cream with vegetable oil would be misleading because consumers expect sour cream to be a dairy product. Similarly, consumers would be misled if a fat analog from a

vegetable source replaced the milkfat in sour cream.

7. Ingredients Prohibited By the Reference Standard

36. Several comments opposed proposed § 130.10(d)(3), which states that an ingredient or component of an ingredient that is specifically prohibited by the standard cannot be added to a substitute food under this section.

Two comments requested that proposed § 130.10(d)(3) be made more flexible. One comment stated that the use of nutritionally insignificant amounts of ingredients, such as colorings and flavorings, could be permitted in § 130.10 foods, even if they are specifically forbidden by a standard of identity, to enhance the consumer acceptance of the substitute food. Another comment requested that FDA permit the use of flavorings simulating the flavor of a cheese of any age or variety in reduced fat versions of pasteurized process cheese to achieve a similar product to the traditional full fat counterpart.

FDA disagrees that safe and suitable ingredients specifically prohibited by a standard should be provided for in a substitute food under new § 130.10. There are valid reasons why these ingredients were specifically excluded in the traditional standard (e.g., economic deception or inappropriateness for the type of food). However, in some cases there are other quality ingredients that may be added for the same purposes.

For example, the agency finds that simulated cheese flavors are unsuitable for use in cheese and related cheese products. Although new § 130.10(d)(1) would permit ingredients to add flavor in substitute foods, flavoring ingredients that are specifically prohibited by standards of identity from inclusion in such foods are specifically prohibited in the modified form of such food (new § 130.10(d)(3)). The standard of identity for pasteurized process cheese in § 133.169(d)(6) specifically excludes any flavorings that, singly or in combination with other ingredients, simulate the flavor of a cheese of any age or variety from use in such food. However, "safe and suitable enzyme modified cheese" may provide a source of flavor in pasteurized process cheese, and this source of flavor is one of the optional ingredients that the agency now permits in this food, as specified in § 133.169(d)(9).

37. One comment asked that the use of "skim milk cheese for manufacturing" in § 133.189 be permitted in the formulation of fat-modified pasteurized process cheese, even though the standard of identity in § 133.169 does not now provide for this lower fat, "traditional" dairy ingredient.

FDA disagrees with this comment. Although skim milk cheese for manufacturing is an ingredient in the same class as other cheese ingredients used in the manufacture of the pasteurized process cheese products, because the standard for pasteurized process cheese (§ 133.169) specifically prohibits the use of this ingredient, this lower fat cheese ingredient may not be used in modified versions of this food. Manufacturers wanting to utilize this ingredient in pasteurized process cheese products must label the product as a nonstandardized food or, if appropriate, as pasteurized process cheese food (§ 133.173) or a modified version of pasteurized process cheese food.

Persons interested in providing for the use of skim milk cheese for manufacturing in modified versions of pasteurized process cheese (§ 133.169) may petition the agency to amend the standard.

H. Nomenclature

38. Several comments stated that they believed that allowing the use of the name of a standardized food on foods to which additional safe and suitable ingredients are added is deceiving to consumers, in direct conflict with the standards of identity concept/procedure, and should not be permitted. Comments stated that if FDA is going to permit optional ingredients to be added to standardized foods to accomplish the performance criteria cited in proposed § 130.10(d)(1), it should require that terms such as "substitute" or "modified" be used in the name of the food.

FDA disagrees with these comments. The major ingredients in a substitute food under new § 130.10 must be ingredients mandated by the relevant standard of identity. The only deviations from the standard that are authorized are those that are necessary to make the nutrient content claim, to ensure that the food meets the performance characteristics of the traditional standardized food, and to ensure the food is not nutritionally inferior to the traditional standardized food. FDA believes that the use of the nutrient content claim in the name of the food and the use of asterisks in the ingredient statement will alert consumers to the fact that the food contains ingredients that differ from those found in the standardized food. Therefore, FDA concludes that consumers will be adequately informed of differences between the § 130.10 food and the traditional standardized food. Because the § 130.10 food is itself a standardized food, it does not need to be labeled as a substitute.

39. One comment requested that the agency clarify that use of "substitute," "alternate," and a distinctive common or usual name remain viable for naming nonstandardized foods. Another comment stated that FDA should require the use of the term "substitute" in conjunction with a standardized name of a food when one or more of the basic characterizing ingredients of a standardized dairy food has been replaced with nondairy ingredients (e.g., vegetable oil in place of milkfat).

FDA notes that § 101.3(e)(4) requires that a food that resembles a standardized food but does not comply with the standard of identity must be labeled as imitation if it is nutritionally inferior to the food, or as a substitute or alternative if it is not nutritionally inferior. As stated above, foods that comply with new § 130.10 comply with a standard of identity.

New § 130.10(d)(2) prohibits the use of functionally similar ingredients to replace an ingredient that is specifically required by the standard. Therefore, a lowfat substitute for mozzarella cheese that is made with vegetable oil would have to be labeled as "imitation mozzarella cheese" if it is nutritionally inferior to mozzarella cheese, or "mozzarella cheese substitute" or "mozzarella cheese alternative" if it is not nutritionally inferior to mozzarella cheese because it does not comply with the standard of identity for mozzarella cheese (§ 133.155) or with new § 130.10.

40. One comment stated that FDA should clearly indicate that any applicable modifier may be used if more than one is applicable.

FDA agrees that any applicable nutrient content claim, if defined by FDA, may be used if more than one is applicable.

41. Two comments stated that if the name of a standardized food, coupled with the nutrient content claim, presents a contradiction in terms (e.g., nonfat ice cream), then the use of such nutrient content claim should be restricted. One comment added that standardized dairy products (e.g., ice cream) should not be reformulated to the extent that they lose their "dairy product" identity (e.g., nonfat ice cream). They would become "nondairy" products and should be named accordingly.

FDA disagrees with these comments. In the January 22, 1991, ANPRM (56 FR 2149) concerning the filing of several petitions to amend the standards for ice cream and ice milk and to establish standards for reduced fat, low fat, and

nonfat ice creams. FDA received comments in response to the ANPRM concerning whether the use of the terms "reduced fat ice cream," "low fat ice cream," and "nonfat ice cream" is misleading to consumers.

Several comments received in response to the ANPRM maintained that consumers will recognize "reduced fat ice cream," "low fat ice cream," and "nonfat ice cream" as products that, while containing less fat than ice cream, will deliver what they have come to expect from that food, i.e., similar taste, appearance, mouthfeel, and nutrition as ice cream products. The comments also noted that the nutrition labeling on the reduced fat products will provide additional information on the fat content of the products for comparison purposes.

As noted in these comments on the ANPRM, consumers have had experience for many years with the term "nonfat" on other dairy products (e.g., nonfat milk and nonfat yogurt). In addition, FDA has issued a number of temporary marketing permits and an extension of a temporary marketing permit for "nonfat cottage cheese," a mixture of dry curd cottage cheese with a dressing that contains less than 0.5 percent of milkfat, and has granted temporary marketing permits for "no fat sour cream." FDA believes that these products are dairy products even though milkfat has been reduced or removed because the milkfat is replaced with skim milk or other dairy ingredients. Nutrition labeling will also assist consumers in making value comparisons relative to the fat reduction as well as calorie reductions in these foods. Therefore, FDA concludes that consumers will not be confused or misled by the use of the nutrient content claim "nonfat" in conjunction with a standardized term such as "ice cream."

42. One comment disagreed with the prohibition on the use of a name permitted on a food under the new generic standard of identity if that food complies with another standard. It stated that this prohibition is a barrier to directing consumers to lower fat versions of products with which they are familiar. It stated that if a modified product meets a traditional standard and the general standard, food producers should be given the option of naming the food using any of the terms allowed under those standards.

FDA disagrees that the name of a modified food that meets the requirements of another standard in parts 131 through 169 should be either name. The common or usual name of a food that has been defined by a standard of identity under section 401 of the act is the name prescribed by the standard. Foods that comply with any standard in parts 131 through 169 must use that standardized name, and this rulemaking is not intended to amend existing standards nor create duplicative standards.

As FDA stated in the proposal (56 FR 60512 at 60520), comparative labeling in accordance with regulations in part 101 may be used to provide consumers with useful information in the selection of a variety of foods.

I. Ingredient Labeling

In the proposal, FDA requested comments on the proposed approach to ingredient labeling in proposed § 130.10(f) and on other methods of identifying ingredients not provided for by the traditional standard of identity (56 FR 60512 at 60520).

43. A number of comments objected to the proposed labeling requirements that ingredients not in the standardized food be highlighted with an asterisk, with a statement following the ingredient statement. One comment urged FDA not to establish the specific words that processors must use to convey information about the amount of ingredients not in the standardized food. Several comments stated that consumers generally are not concerned about, or even interested in, how these formulations are achieved, and that the use of asterisks and label statements may be potentially confusing. Several comments stated that the proposed ingredient disclosures would be burdensome to manufacturers and would result in label clutter.

The agency also received comments strongly supporting the use of the disclosures as meaningful steps in the goal of consumer information and understanding. One comment stated that food companies need to inform the consumer as to whether adjustments have been made to their products, and that the item is no longer the same as the standardized food. It stated that the simple labeling of a product as "low fat" is not sufficient because this claim may give the consumer the impression that the product is the same as always, but contains less fat, which may or may not be true.

FDA disagrees with the comments that opposed the use of asterisks. Standards of identity regulations are established when such action will promote honesty and fair dealing in the interest of consumers. The highlighting of ingredients that are not part of the traditional standard of identity, or that are added in excess of what is permitted by that standard, is appropriate to ensure continued consumer confidence in standardized foods. FDA believes that under sections 201(n) and 403(d) of the act, consumers are entitled to know how the new standardized food differs from the traditional standardized food. In some cases, consumers may have allergies to certain ingredients that may not be normally encountered in the standardized food. Therefore, FDA finds that these ingredients must be highlighted.

44. Many comments stated that it is important for persons with hemochromatosis to know when iron is added to a food. They stated that added iron is often more biologically available than other forms of iron. Several of the comments opposed the language of proposed § 130.10(f)(2) that exempts added iron from being identified with an asterisk in the ingredient statement.

Any added iron must be listed as an ingredient in the ingredient statement. As stated in the proposal (56 FR 60512 at 60520), the consumer may be misled to believe that ingredients added to restore nutrients are present in greater amounts than needed to obtain nutritional equivalency if these nutrients are identified with an asterisk in the ingredient statement. Iron is added to a number of foods, not just standardized foods including foods under new § 130.10. Most § 130.10 foods to which iron will need to be added to ensure that the product is not nutritionally inferior are foods that must contain added iron under the traditional standard of identity (e.g., enriched bread, rolls, and buns (§ 136.115)). The agency notes that nutrition labeling will inform consumers of any iron present in significant amounts in the food. Thus, FDA concludes that persons with hemochromatosis will be adequately informed of added iron in any food, and that the use of an asterisk in the ingredient statement is not necessary for nutrients added to a § 130.10 food.

45. Two comments stated that FDA should require that the principal display panel of the label contain a referral statement directing consumers to the ingredient statement to be informed of any nonstandard ingredients. One comment recommended that this statement should be tailored to different types of foods, based on the ingredients that characterize the foods to consumers. For example, the comment noted, dairy products could be labeled with the term "made with nonstandard nondairy ingredients." In addition, the comment stated that products that meet the nutrient content claim requirements, but are made only from standard ingredients, could be permitted to use the term "pure" as part of the common

or usual name ("pure reduced fat sour cream").

The agency disagrees with these comments. FDA believes that this additional labeling is not necessary because the ingredients that are not in the traditional standardized food are already identified with an asterisk in the ingredient statement. FDA also disagrees with this use of the term "pure." The agency has not defined the term "pure" and believes that the use of the term in the requested manner could cause consumer confusion because of its ambiguity.

46. One comment stated that if these products contain saccharin, aspartame, or acesulfame potassium, they should clearly state this fact on the front label.

FDA notes that a product is misbranded under section 403(o)(1) of the act if it contains saccharin, unless, its label and labeling bear the following statement: "USE OF THIS PRODUCT MAY BE HAZARDOUS TO YOUR HEALTH. THIS PRODUCT CONTAINS SACCHARIN WHICH HAS BEEN DETERMINED TO CAUSE CANCER IN LABORATORY ANIMALS." This statement must be located in a conspicuous place on the label and labeling, as proximate as possible to the name of such food, and must appear in conspicuous and legible type in contrast by typography, layout, and color with other printed matter on such label and labeling.

FDA also notes that § 172.804 (21 CFR 172.804) requires that the label of any food containing aspartame bear, either on the principal display panel or on the information panel, the following statement: "PHENYLKETONURICS: CONTAINS PHENYLALANINE." The statement must appear in the labeling prominently and conspicuously as compared to other words, statements, designs or devices and in bold type and on clear contrasting background in order to render it likely to be read and understood by the ordinary individual under customary conditions of purchase and use.

The regulation in § 172.800 (21 CFR 172.800) concerning acesulfame potassium requires no special label statements. However, whenever acesulfame potassium, aspartame, or saccharin are ingredients in a food, the name of the ingredient must appear in the ingredient declaration according to part 101.

The comment did not provide any basis for requiring special label statements concerning the addition of these sweeteners for foods subject to new § 130.10. FDA believes that the above requirements provide adequate notice of the presence of these ingredients when they are used. Therefore, FDA concludes that no additional statements need be required other than those that are required by the act and current FDA regulations, including the use of asterisks and label statements required in new § 130.10(f)(2).

J. Label Format

47. Two comments suggested that FDA should develop more simplified principal display panel labeling requirements and consider a mandatory format for comparative labeling of § 130.10 foods. The comment gave the following example: Reduced Fat "Modified" Cheddar Cheese; 25 percent Less Fat than Cheddar Cheese; Side panel provides nutrition information, per serving size comparisons, and nonstandardized (*) ingredients.

FDA disagrees with this comment. The principal display panel labeling requirements for use of nutrient content claims are mandated by the 1990 amendments and regulations in part 101 concerning the claim. New § 130.10(c) requires additional labeling on the principal display panel only when there are differences in performance characteristics. FDA concludes that the requirements that it is adopting are the minimum necessary to ensure that the labeling of § 130.10 foods is informative, adequate, and not misleading. In addition, FDA believes that except as provided in new § 130.10(c), it is not necessary to mandate a particular format for the principal display panel.

K. Existing Standards Using Nutrient Content Claims

48. One comment expressed concern about FDA's tentative decision to exclude from this rule standards of identity that already incorporate nutrient content claims (e.g., lowfat milk). Another comment stated that FDA should give serious consideration to eliminating the existing standards of identity for those foods that have a nutrient content claim as part of their standardized names, in cases where the remainder of the name is also a standardized term.

The agency appreciates the concerns expressed in these comments. FDA did not include existing standards in the proposal to this final rule because Congress exempted nutrient content claims that are part of the name of a food defined by an existing standard of identity even if the use of the term in the standardized name is not consistent with the definition for the term that FDA adopts (section 403(r)(5)(C) of the act). However, the legislative history makes clear that this exemption was included in the law because of the preexisting standards of identity and the possibility that these standards would conflict with the definitions adopted under the new law. The legislative history goes on to state that to the extent that those standards do provide definitions that are different from the definitions in the regulations issued by FDA under the 1990 amendments, one basic purpose of the 1990 amendments will be partially undermined. Therefore, the legislative history points out that the Secretary (and, by delegation, FDA) has the authority to correct this problem by amending the standards of identity to conform with the regulations issued under section 403(r) of the act (H. Rept. 101–538, 101st Cong., 2d sess. 22 (June 13, 1990)).

FDA will consider amending the existing standards of identity that use nutrient content claims in a food name to make them consistent with the definitions that the agency is adopting. The agency's options include amending standards of identity to comply with the nutrient content claim or deleting some standards and allowing the use of these claims with standardized terms in accordance with new § 130.10. Thus, FDA does intend to consider taking the actions suggested by these comments, although it is unable to do so at this time.

L. Legal and Policy Analysis

49. One comment stated that the same legal and policy analysis applies to foods that substitute for foods standardized by statute as to foods that substitute for foods standardized by regulation. It suggested that the preamble to the final rule adding new § 130.10 state that the same legal and policy analysis applies to foods subject to new § 130.10 as to foods subject to § 101.67.

FDA disagrees with this comment. Butter, nonfat dry milk, milk, and oleomargarine or margarine are foods that have been defined by statute. Under section 401 of the act, FDA has modified the definitions and has established standards of identity for nonfat dry milk, milk, and oleomargarine or margarine. However, under section 401 of the act, FDA is prohibited from establishing standards for butter. Therefore, the legal and policy analysis of butter is different from foods standardized by regulation. Proposed § 101.67 deals only with the use of nutrient content claims for butter. FDA can establish standards for other foods under section 401 of the act, and terms that are standardized by regulation are those that may be used under new § 130.10.

III. Pending Petitions

As stated in the proposal (56 FR 60513 at 60516), FDA has received petitions from: (1) The Milk Industry Foundation (MIF) (Docket No. 88P–0329), H. P. Hood, Inc. (Docket No. 89P–0105), and Crowley Foods, Inc. (Docket No. 89P–0403) to establish a standard for "light sour cream;" (2) MIF (Docket No. 88P–0334) and H. P. Hood, Inc. (Docket No. 89P–0329) to establish a standard for "light eggnog;" and (3) the International Ice Cream Association (IICA), the Public Voice for Food and Health Policy, Kraft General Foods, and the Calorie Control Council to amend the standards for "ice cream" and "ice milk" and to establish standards for "reduced fat ice cream," "lowfat ice cream," and "nonfat ice cream" (Docket No. 88P–0251).

FDA has received a number of applications from companies desiring to market test "nonfat cottage cheese." The agency has issued approximately 22 temporary marketing permits for the product. MIF filed a petition, dated November 2, 1991 (Docket No. 91P–0448), to establish a standard of identity for "nonfat cottage cheese." MIF stated in its petition that establishing a standard of identity for "nonfat cottage cheese" would enhance public health, satisfy consumer demand, and promote honesty and fair dealing in the interest of consumers.

All of the petitions are requesting that the agency establish standards for modified versions of traditional standardized foods. Nutrient content claims for the fat content of foods are defined in § 101.62 and include "nonfat" (§ 101.62(b)(1)), "low fat" (§ 101.62(b)(2)), and "reduced fat" (§ 101.62(b)(4)). The term "light" or "lite" is defined in § 101.56. New § 130.10 establishes the requirements for use of these defined nutrient content claims with a standardized term. Therefore, the agency is responding to the above petitions by adopting this final rule. However, new § 130.10 does not encompass some portions of the petitions to amend the standards for ice cream and ice milk. Therefore, FDA is responding to those portions of the petitions to amend the standards for ice cream and ice milk in a separate proposal published elsewhere in this issue of the **Federal Register**.

50. One comment requested that to ensure that there is consistency in nomenclature regarding nutrient modified ice creams, FDA should take final action on the petition from the IICA to establish specific standards for modified ice creams and defer the applicability of the provisions of the 1990 amendments to the products within the scope of the IICA petition until 12 months after: (1) The effective date of regulations that FDA adopts in response to the IICA petition, or (2) FDA takes final action to reject the petition, whichever is applicable.

The agency disagrees with the comment. The standard of identity for ice milk (§ 135.120) states that its milkfat content is more than 2 percent but not more than 7 percent. The agency realizes that some reduced fat ice cream products may comply with the standard of identity for ice milk and must be labeled as "ice milk." As stated above, elsewhere in this issue of the **Federal Register**, FDA is proposing changes in the standards of identity for ice cream and ice milk. The agency is proposing to repeal the standard of identity for ice milk. If FDA repeals the standard for ice milk, manufacturers would be able to label ice cream products containing more than 2 percent but not more than 7 percent milkfat according to new § 130.10.

Because FDA is taking action on the IICA petition at this time, it does not believe that deferring the applicability of the provisions of new § 130.10 for ice cream products is necessary.

IV. Noncharacterizing Changes in Standardized Foods

51. One comment stated that because the use of nutrient content claims is voluntary, and because the standardized name alone is a proper statement of identity for a standardized food, the suggested use and placement of any nutrient content claim in conjunction with the name of a standardized food that meets the requirements of the standard of identity would, of course, be optional.

FDA agrees with this comment. The labeling for foods meeting a standard of identity and qualifying for the use of a nutrient content claim must comply with the respective standard of identity in parts 131 through 169 and the requirements of § 101.13 concerning nutrient content claims. Because these foods are not modified foods, they do not fall within the scope of new § 130.10. Therefore, FDA concludes that the use of a nutrient content claim in the name of a food complying with a standard of identity is not mandatory. For example, reduced cholesterol liquid eggs may still comply with the standard for liquid eggs (§ 160.115) although part or all of the cholesterol has been removed. The nutrient content claim "reduced cholesterol" may appear as part of the statement of identity in conjunction with the standardized name, or it may appear elsewhere on the label, according to applicable sections of part 101, with the statement of identity consisting of the standardized name.

V. Conclusion

In response to comments submitted regarding the proposal for requirements for foods named by use of a nutrient content claim and a standardized term (56 FR 60512), FDA has revised new § 130.10. The following summarizes the changes being made to new § 130.10 by this final rule:

FDA has revised the title of the regulation to delete the term "substitute" because new § 130.10 applies only to a certain category of substitute foods and not all types of substitute foods as defined under § 101.3(e)(4) and § 101.13(d).

FDA has revised new § 130.10(a) to more clearly establish the scope of the regulation by adding that § 130.10 foods use the name of the traditional standardized food in their statement of identity but do not comply with the traditional standard.

The agency has revised new § 130.10(a) to state that the deviation from the standard of identity "is described by an expressed nutrient content claim that has been defined by FDA regulation."

FDA has revised the last sentence of new § 130.10(a) to read: "The food shall comply with the relevant standard in all other respects except as provided in paragraphs (b), (c), and (d) of this section."

FDA has added a new sentence to new § 130.10(c) at the beginning of the paragraph to state: "Deviations from noningredient provisions of the standard of identity (e.g., moisture content, food solids content requirements, processing conditions) are permitted in order that the substitute food possesses performance characteristics similar to those of the standardized food." In addition, FDA has included in new § 130.10(c) a requirement that deviations from ingredient and noningredient provisions of the standard must be the minimum necessary to achieve this effect or the food will be deemed to be adulterated under section 402(b) of the act.

The agency has added a statement to new § 130.10(c) to require that the modified product must perform at least one of the principal functions of the standardized product substantially as well as the standardized product.

The agency has also revised new § 130.10(c) by limiting the labeling requirement to changes that materially affect the use of the product.

Finally, FDA has revised new § 130.10(c) to require that the mandated

label statement concerning any differences in performance characteristics be in accordance with the requirements of § 101.13(d).

The agency has revised new § 130.10(d)(1) to include the use of safe and suitable ingredients to improve appearance and to add sweetness.

FDA has added new § 130.10(d)(4) to state that an ingredient specifically required by the standard as defined in parts 131 through 169 must be present in a significant amount. A significant amount of an ingredient is at least that amount that is required to achieve the technical effect provided by that ingredient in the modified food.

The agency has added new § 130.10(d)(5) to provide for the use of water and safe and suitable fat analogs in accordance with new § 130.10(c), (d)(1), and (d)(2) in modified foods to replace fat and calories.

FDA has revised new § 130.10(e) to state that the name of the substitute food "is the appropriate expressed nutrient content claim and the applicable standardized term."

VI. Environmental Impact

The agency previously considered the environmental effects of the action being taken in this final rule. As announced in the reproposed rule for mandatory nutrition labeling (56 FR 60366, November 27, 1991) and the proposed rule for nutrient claims (56 FR 60421, November 27, 1991), the agency determined that under 21 CFR 25.24(a)(8) and (11), these actions are of a type that do not individually or cumulatively have a significant impact on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement was required.

Several comments on the proposed rule suggested that there would be significant adverse environmental effects from the final rules unless the agency allowed more time between the publication of the final rules and their effective dates. The concern in these comments was that, if the agency did not allow firms more time between the publication of the final rules and their effective dates to use up existing label inventories, large stocks of labels and labeled packaging would have to be discarded. These comments questioned whether the agency had sufficiently examined the impact of disposing of obsolete labels and labeled packaging on this country's solid waste disposal capabilities. Two comments estimated the amounts of labeling from their respective industries, i.e., dairy and confectionery, that would need to be discarded following publication of FDA's final rules on several food labeling actions, including this action. However, these comments did not: (1) provide details on how these estimates were derived, (2) identify what portion of the estimated amounts are attributable to these two actions, or (3) describe what impact the discarded labels and packaging would have on the disposal of solid waste. In its November 27, 1991, reproposed rule for mandatory nutrition labeling and proposed rule for nutrient content claims, the agency proposed that the final rules for these actions would become effective 6 months following their publication in the **Federal Register**.

However, the agency has decided to allow additional time for companies to use up their old labels. Thus, the final rule will not be effective until May 8, 1994. FDA believes there will thus be ample time for food companies to use up most of the existing labeling and packaging stocks and to incorporate labeling language that complies with FDA's regulations into their food labels. Consequently, the comments on the potential for adverse environmental effects do not affect the agency's previous determination that no significant impact on the human environment is expected and that an environmental impact statement is not required.

VII. Economic Impact

In its November 27, 1991, food labeling proposals (56 FR 60366), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the Federal Register of November 27, 1991 (56 FR 60856), along with the food labeling proposals, and the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 130

Food additives, Food grades and standards.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 130 is amended as follows:

PART 130—FOOD STANDARDS: GENERAL

1. The authority citation for 21 CFR part 130 continues to read as follows:

Authority: Secs. 201, 306, 401, 403, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 336, 341, 343, 371).

2. Section 130.10 is added to subpart A to read as follows:

§ 130.10 Requirements for foods named by use of a nutrient content claim and a standardized term.

(a) *Description.* The foods prescribed by this general definition and standard of identity are those foods that substitute (see § 101.13(d) of this chapter) for a standardized food defined in parts 131 through 169 of this chapter and that use the name of that standardized food in their statement of identity but that do not comply with the standard of identity because of a deviation that is described by an expressed nutrient content claim that has been defined by FDA regulation. The nutrient content claim shall comply with the requirements of § 101.13 of this chapter and with the requirements of the regulations in part 101 of this chapter that define the particular nutrient content claim that is used. The food shall comply with the relevant standard in all other respects except as provided in paragraphs (b), (c), and (d) of this section.

(b) *Nutrient addition.* Nutrients shall be added to the food to restore nutrient levels so that the product is not nutritionally inferior, as defined in

§ 101.3(e)(4) of this chapter, to the standardized food as defined in parts 131 through 169 of this chapter. The addition of nutrients shall be reflected in the ingredient statement.

(c) *Performance characteristics.* Deviations from noningredient provisions of the standard of identity (e.g., moisture content, food solids content requirements, or processing conditions) are permitted in order that the substitute food possesses performance characteristics similar to those of the standardized food. Deviations from ingredient and noningredient provisions of the standard must be the minimum necessary to qualify for the nutrient content claim while maintaining similar performance characteristics as the standardized food, or the food will be deemed to be adulterated under section 402(b) of the act. The performance characteristics (e.g., physical properties, flavor characteristics, functional properties, shelf life) of the food shall be similar to those of the standardized food as produced under parts 131 through 169 of this chapter, except that if there is a significant difference in performance characteristics that materially limits the uses of the food compared to the uses of the standardized food, the label shall include a statement informing the consumer of such difference (e.g., if appropriate, "not recommended for cooking"). Such statement shall comply with the requirements of § 101.13(d) of this chapter. The modified product shall perform at least one of the principal functions of the standardized product substantially as well as the standardized product.

(d) *Other ingredients.* (1) Ingredients used in the product shall be those ingredients provided for by the standard as defined in parts 131 through 169 of this chapter and in paragraph (b) of this section, except that safe and suitable ingredients may be used to improve texture, add flavor, prevent syneresis, extend shelf life, improve appearance, or add sweetness so that the product is not inferior in performance characteristics to the standardized food defined in parts 131 through 169 of this chapter.

(2) An ingredient or component of an ingredient that is specifically required by the standard (i.e., a mandatory ingredient) as defined in parts 131 through 169 of this chapter, shall not be replaced or exchanged with a similar ingredient from another source unless the standard, as defined in parts 131 through 169 of this chapter, provides for the addition of such ingredient (e.g., vegetable oil shall not replace milkfat in light sour cream).

(3) An ingredient or component of an ingredient that is specifically prohibited by the standard as defined in parts 131 through 169 of this chapter, shall not be added to a substitute food under this section.

(4) An ingredient that is specifically required by the standard as defined in parts 131 through 169 of this chapter, shall be present in the product in a significant amount. A significant amount of an ingredient or component of an ingredient is at least that amount that is required to achieve the technical effect of that ingredient in the food.

(5) Water and fat analogs may be added to replace fat and calories in accordance with § 130.10(c), (d)(1), and (d)(2).

(e) *Nomenclature.* The name of a substitute food that complies with all parts of this regulation is the appropriate expressed nutrient content claim and the applicable standardized term.

(f) *Label declaration.* (1) Each of the ingredients used in the food shall be declared on the label as required by the applicable sections of part 101 of this chapter and part 130.

(2) Ingredients not provided for, and ingredients used in excess of those levels provided for, by the standard as defined in parts 131 through 169 of this chapter, shall be identified as such with an asterisk in the ingredient statement, except that ingredients added to restore nutrients to the product as required in paragraph (b) of this section shall not be identified with an asterisk. The statement "*Ingredient(s) not in regular _____" (fill in name of the traditional standardized food) or "*Ingredient(s) in excess of amount permitted in regular _____" (fill in name of the traditional standardized food) or both as appropriate shall immediately follow the ingredient statement in the same type size.

Dated: October 27, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Food and Drug Administration

21 CFR Part 101

[Docket No. 91N–0344]

RIN 0905–AD08

Food Labeling: Use of Nutrient Content Claims for Butter

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is adopting a regulation that will permit nutrient content claims that are defined by regulation in 21 CFR part 101 to be made for butter. This action is in response to the Nutrition Labeling and Education Act of 1990 (the 1990 amendments).

EFFECTIVE DATE: May 8, 1994.

FOR FURTHER INFORMATION CONTACT: Shellee A. Davis, Center for Food Safety and Applied Nutrition (HFS–158), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–5112.

SUPPLEMENTARY INFORMATION:

I. Background

In response to the 1990 amendments (Pub. L. 101–535) and to a citizen petition submitted by Johanna Farms, Inc., Flemington, NJ 08822, (Docket No. 90P–0141), FDA published in the **Federal Register** of November 27, 1991 (56 FR 60523), a proposal to adopt § 101.67, which would permit nutrient content claims that are defined by regulation in part 101 (21 CFR part 101) to be made for butter. Interested persons were given until February 25, 1992, to comment on this proposed regulation.

FDA received approximately 70 responses on the proposal, each of which contained one or more comments, from trade and retail associations, government organizations, manufacturers, consumers, retailers, consumer groups, State groups, private organizations, professional societies, and universities. The comments generally supported the proposal. Several comments addressed issues outside the scope of the proposal (e.g., serving size and nutrient content claims definitions) and will not be discussed here. A number of comments suggested modification and revision in various provisions of the proposal. A summary of the suggested changes and the agency's responses follow.

II. Use of Nutrient Content Claims for Butter Under the 1990 Amendments

A. The Proposed Approach

FDA requested comments on its proposed approach to permit nutrient content claims to be made for butter (56 FR 60523 at 60525).

1. Two comments stated that FDA had the authority to promulgate § 101.67 independent of the 1990 amendments. One of the comments said that a better approach would have been under the general provisions of proposed § 130.10 or through a standard of identity. It stated that a food that does not meet the statutory standard for butter is not butter, and that accordingly, a product with less milkfat simulating butter would need to be labeled "imitation" in the absence of some other governing agency mechanism, such as a standard of identity for "light butter." The comment maintained that since "light" would be part of the name, the product would not be butter because the definition would be different. The product would not be nutritionally inferior, the comment continued, because it would be required to provide the same nutrients as butter (except for less fat), and it would not be deceptive because properly informative labeling would be required and monitored by the agency.

The agency disagrees with the comments. As explained in the proposal (56 FR 60523 at 60524), the agency does not have the authority to establish a definition and standard of identity for "light butter." Section 401 of the Federal Food, Drug, and Cosmetic Act (the act) (21 U.S.C. 341) states that no definition and standard of identity can be established for butter. Moreover, FDA has historically taken the position that a product using the term "butter" must comply with the statutory definition of butter, or its labeling would be false, and it would be misbranded under section 403(a)(1) of the act (21 U.S.C. 343(a)(1)) (see 56 FR 60523 at 60524). In addition, a food sold under the name "butter" that does not comply with the statutory standard for butter also is in violation of section 403(b) of the act in that it is sold under the name of another food.

As discussed in the proposed rule, FDA sought an interpretation that gave effect both to section 3(b)(1)(A)(viii) of the 1990 amendments (21 U.S.C. 343 note), which stated that FDA could establish a regulation that would permit a nutrient content claim, such as "light," to be made for butter, and to section 401 of the act. FDA believes that it achieved this goal in proposed § 101.67. These comments, since they rely on section 401 of the act, have not provided any basis to conclude to the contrary.

2. A number of comments opposed providing for the use of nutrient content claims for butter. Several comments recommended that the term "butter" be used only if the product complies with the statutory standard for butter, and that other names such as "dairy spread" be used for other butter products. Some comments stated that if a product is good it will develop its own distinctive name.

The agency understands the concerns expressed by these comments. However, the 1990 amendments and their legislative history make clear that Congress fully intended that a claim described in section 403(r)(1)(A) of the act (such as "light") be permitted to be made for butter (H. Rept. 101–538, 101st Cong., 2d sess. 22–23 (June 13, 1990)). Given this fact, there is no basis to require the use of terms such as "dairy spread" in the common or usual names of these products. Accordingly, FDA is allowing, as proposed, nutrient content claims to be made for butter.

B. The Nutrient Content Claim

3. Several comments expressed concern about consumers being able to identify butter products on the store shelf. The comments were concerned that nutrient content claims could mislead and confuse consumers even if they are defined.

The agency appreciates the concerns expressed by the comments. In response to the requirements of the 1990 amendments, published elsewhere in this issue of the **Federal Register**, in a document entitled "Food Labeling: Nutrient Content Claims, General Principles, Petitions, Definitions of Terms" (hereinafter referred to as the nutrient content claims final rule), FDA is establishing in part 101 definitions for nutrient content claims together with general principles governing their use. FDA has carefully considered each nutrient content claim to ensure that these definitions will be meaningful to consumers. Each of the definitions for the nutrient content claims also prescribes specific labeling that must accompany the claim. The agency believes that as consumers learn what a claim means, they will be able to understand that a product such as "light butter" is reduced a certain amount in fat. Thus, the use of nutrient content claims for butter products in accordance with new § 101.67 will not mislead or confuse consumers but will assist them in maintaining healthy dietary practices.

New § 101.67 only provides for the use for butter of nutrient content claims

that have been defined by FDA. Any product labeled as "butter" that does not come within the provisions of new § 101.67 will need to comply with the statutory standard for butter, or its labeling will be false, and it will be misbranded under the act.

FDA notes, however, that there are two potential problems that proposed § 101.67 failed to address that could cause confusion among consumers. In the proposal, FDA did not require that the nutrient content claim be included as part of the statement of identity of the butter product. Consequently, a claim could be made for the butter product in an inconspicuous location on the label, and consumers could be misled about the identity of the product that does not comply with the statutory standard for butter (section 201a of the act (21 U.S.C. 321a)).

In addition, FDA did not distinguish between express and implied claims in the proposal. Yet section 403(r)(1)(A) of the act applies to both types of nutrient content claims.

Therefore, to rectify this potential confusion, FDA is adding § 101.67(a)(4) to make clear that while nutrient content claims may be made anywhere on the label, if the product would violate section 201a of the act but for the nutrient content claim that characterizes the level of nutrients, that claim must be included as part of the common or usual name of the product. This provision will ensure that consumers are not misled about the identity of the product.

New § 101.67(a)(4) also provides that if the name of the butter product is necessary to distinguish it from butter, the claim must be an express claim as defined in new § 101.13(b)(1). If the claim is not express, consumers will not understand how the new modified food differs from the traditional food. Thus, only expressed nutrient content claims may be used in the name of the food under new § 101.67. While implied claims may be used as provided in new § 101.13(b)(2), they may not be used in conjunction with the name of the butter product because they would not be adequately informative to consumers.

4. One comment stated that FDA should decide on a more appropriate name than "light butter," such as "light butter product."

The agency does not believe the suggested additional term (i.e., "product") is necessary. If a butter product does not comply with the statutory standard for butter or the requirements of new § 101.67 set forth below, FDA requires that it be labeled either as an imitation food if it is nutritionally inferior to butter (§ 101.3(e)(1)), or as a substitute or alternative food if it is not nutritionally inferior to the food for which it substitutes, with an appropriately descriptive common or usual name that is not false and misleading, as provided for in § 102.5 (21 CFR 102.5), or, in the absence of an existing common or usual name, an appropriately descriptive term that is not false and misleading (§ 101.3(e)(2) (21 CFR 101.3(e)(2))). As explained above in comment 2 of this document, the legislative history of the 1990 amendments makes clear that Congress fully intended that a claim described in section 403(r)(1)(A) of the act (such as "light") be permitted to be made for butter (H. Rept. 101–538, supra, 22–23). Given this fact, there is no basis to require the use of additional terms such as "product" in the common or usual names of these foods. The use of a nutrient content claim that is permitted by regulation with the term "butter" in the statement of identity will provide a clear indication to consumers that the food is different from traditional butter and will describe the nature of the modification. In addition, the label must comply with all the requirements for the use of the nutrient content claim. Accordingly, the agency is not making the suggested modification to new § 101.67.

5. A number of comments suggested that FDA should develop unique nutrient content claims for butter because the proposed nutrient content claim requirements for fat in proposed § 101.62 are not appropriate or realistic for butter products. Two comments added that the use of unique nutrient claims for butter is consistent with the directive in the President's Executive Order 12630 that regulations harness the mechanisms of the market (e.g., competition in percentage reductions) to accomplish the agency's goal. One comment stated that it had test marketed a 50-percent reduced fat butter for over a year, but that the product failed to meet consumers' expectations, principally in physical performance characteristics. Another comment suggested that a reduced fat butter containing one-third less fat than butter is a product that will significantly reduce fat consumption while having all the characteristics of full-fat butter. The comments urged FDA to adopt simple definitions for nutrient content claims that will allow the industry to make dairy products with less fat and cholesterol available to consumers. One comment noted that a number of states have established regulations for light butter that differ from FDA's proposal. The comment urged FDA to use the knowledge and information obtained by these states in their respective hearing processes to modify FDA's proposed regulations to redefine the term "light" as used with butter products.

FDA notes that because no uniform set of definitions has existed for many nutrient content claims, these claims have been used in an inconsistent manner, which has resulted in consumers being confused and misled. The legislative history of the 1990 amendments makes clear that Congress was aware that many food labels bear terms such as "light" when a product may not be as "light" as the label indicated, or the product was "light" in different ways (e.g., calories or sodium). The purpose of the 1990 amendments was to correct this deceptive and misleading state of affairs by requiring that terms such as "light" have a single meaning (136 Congressional Record H5844, July 30, 1990).

The agency recognizes that because butter is at least 80 percent milkfat, a significant reduction in milkfat produces a significant change in the product. In the nutrient content claims final rule, FDA is redefining "reduced" and "less" to be a reduction of 25 percent or more. Thus, many butter products will be able to meet these requirements and make a nutrient content claim. Also, there is evidence that some manufacturers will be able to meet the 50-percent reduction to qualify for use of the term "light." Thus, FDA sees no reason to create a special set of definitions for butter products under new § 101.67.

FDA recognizes that some states and foreign governments have developed their own definitions for nutrient content claims for butter. However, FDA concludes that use of nutrient content claims in an inconsistent manner would be confusing to consumers, and, thus, the agency is not considering the use of any unique nutrient content claims for butter.

C. Minimum Milkfat Level

In the House report on the 1990 amendments, FDA is directed to consider arguments concerning the appropriate characteristics of butter. In a footnote, the report states:

> The Committee is aware that the dairy industry takes the position that products containing less than approximately 50 percent milkfat lose some of the characteristics of butter. In connection with the promulgation of the regulations, representatives of dairy interests and health experts will have the opportunity to present their views on the issue to the Secretary. (H. Rept. 101–538, supra, 23, n.3.)

In the proposal, FDA requested comments on whether its tentative

decision not to include a minimum milkfat level in proposed § 101.67 was appropriate (56 FR 60523 at 60526).

6. A number of comments concurred with the agency's tentative decision. Comments stated that there is no need to stipulate minimum levels. The comments also stated that not requiring a minimum milkfat level for butter products would leave room for advances in food processing technology that could lead to products with lower levels of milkfat and greater health benefits while still maintaining the characteristics of standardized butter. Another comment concurred as long as the product bearing the term "butter" is describable as a form of butter, because of the fact that its similarities to butter nutritionally, organoleptically, functionally, and in other ways would clearly outweigh its dissimilarities to butter.

One comment stated that FDA should set a minimum butterfat level, below which the product is no longer a butter product. However, the comment did not recommend a minimum level.

FDA agrees with the comments suggesting that a minimum milkfat level is not necessary. A product remains a butter product as long as the major ingredients used in manufacturing it are cream, milk, or constituents of milk and cream and as long as it can be used like butter. In addition, the butter product must comply with all the requirements of new § 101.67 for the use of nutrient content claims for butter products. For example, the milkfat content of butter contributes some of the basic characteristics of the food. New § 101.67(b) provides that the performance characteristics must be similar to those of butter, or the differences must be stated on the principal display panel.

The agency notes that Canadian regulations do not stipulate a minimum milkfat level for "calorie reduced butter."

Therefore, for the above reasons, the agency concludes that there is no need to specify a minimum milkfat level for butter products. The absence of a minimum level will permit technological advances that will provide consumers with butter products that have even greater reductions in fat and calories.

D. Ingredients

FDA requested comments on the use of safe and suitable nondairy ingredients to improve texture, prevent syneresis, add flavor, or extend shelf life. FDA also requested comments concerning the addition of water as well as skim milk, whey, or milk to replace milkfat as an ingredient in substitute butter products. FDA stated in the proposal that if the comments supported the use of safe and suitable nondairy ingredients and provided a substantial basis for their use, FDA might provide for the use of these ingredients in the final rule (56 FR 60523 at 60526).

(1) Safe and Suitable Nondairy Ingredients

7. A number of comments stated that the use of nondairy ingredients should not be permitted. Several comments argued that if manufacturers are adding anything that makes the food something other than butter, it should be labeled as "margarine," "spread," or "margarine." One comment stated that use of nondairy ingredients in a butter product would mislead consumers because consumers expect "butter" to be a dairy product. It added that use of such ingredients would erode the goodwill associated with the term "butter." The comment stated that the fact that current reduced fat butter products made without nondairy ingredients are not satisfactory for some cooking applications is not a reason to permit the use of such ingredients in products whose statement of identity includes the term "butter." It stated that consumers who want reduced fat, reduced calorie products for use in cooking can turn to products properly labeled as margarines and spreads.

Another comment stated that consumers purchasing and using a butter product expect it to be a 100 percent dairy product and thus made from the ingredients and constituents of the ingredients listed in section 201a of the act for standardized butter. It added that use of additional safe and suitable ingredients is not necessary for butter products. It stated that the only exception should be the permitted addition of nutrients to prevent nutritional inferiority and the permitted use of safe and suitable bacterial cultures as proposed in the regulation.

A number of other comments urged FDA to allow the use of safe and suitable nondairy ingredients to improve texture, prevent syneresis, add flavor, or extend the shelf life of the product. One comment stated that FDA should permit the addition of safe and suitable nondairy ingredients that are not fat ingredients for such purposes. Another comment urged FDA to allow the use of safe and suitable ingredients without the restriction that they must be used to maintain the traditional food's performance characteristics as long as the use is in keeping with current good manufacturing practices. The comment stated that the potential need to use safe and suitable ingredients for processing, as well as performance, purposes is most apparent for reformulated butter products because butter is a high fat food, and fat affects processing characteristics as well as final performance characteristics. Several comments argued that providing for the use of safe and suitable ingredients would allow the development of additional products with lower saturated fat, total fat, and cholesterol.

One comment stated that using current technology, "reduced fat" butter made strictly from dairy ingredients is not suitable for frying or baking. It stated that in the event that a "reduced fat" butter made primarily from dairy ingredients cannot be developed with good baking characteristics, then the field needs to remain open to "reduced fat" butter that is made with some nondairy ingredients and that has good baking properties. It added that without these additional ingredients, consumers will have trouble finding "reduced fat" butter that meets their needs and will be discouraged from shifting from full fat to reduced fat butter.

One comment argued that FDA's authority to allow the use of nutrient content claims for butter also gives the agency the authority to allow safe and suitable ingredients, including nondairy ingredients, in a product that is named by using a nutrient content claim with the term "butter." The comment added that FDA has already recognized this authority by providing for two types of ingredients (nutrients and bacterial cultures) in the proposed rule that are not permitted in standardized butter. It urged FDA to modify the regulation consistent with the regulation for substitute foods.

One comment stated that a reduction in milkfat of 50 percent in a butter product made without the use of safe and suitable nondairy ingredients results in a product that fails to meet consumers' expectations for many of the principal uses of a butter product (e.g., baking, frying, melting, sauteing). The comment stated that a light butter product that meets the proposed requirements in proposed § 101.67 (i.e., 50 percent less milkfat than butter and no ingredients other than those allowed in proposed § 101.67) is currently being marketed in Canada. The comment stated that Professor David Bandler of Cornell University testified before the New York Department of Agriculture and Markets regarding a hearing to establish a standard of identity in New York for light butter. The comment stated that Professor Bandler testified that the Canadian light butter product that he evaluated was really a

combination of butter and cream mixed together, and one could easily determine that the product may not be butter for many of the principal uses a consumer would have for butter. (Hearing Transcript, December 4, 1990. State of New York Department of Agriculture and Markets, p. 66.) The comment stated that New York and five other states have established standards for light butter and have provided for the use of safe and suitable nondairy ingredients. The comment urged FDA to allow safe and suitable nondairy ingredients in butter products for which nutrient content claims are made.

Other comments added that use of other safe and suitable ingredients was acceptable as long as the addition of these ingredients is clearly stated on the label and explained in the labeling.

The legislative history of the 1990 amendments makes clear that Congress intended that consumers should be able to use nutrient content claims made for butter to assist them in following dietary guidelines (see H. Rept. 101–538, 101st Cong., 2d sess. 10, 23 (1990)). This intent has two necessary implications. First, Congress obviously intended that FDA adopt provisions that authorize that butter products that bear nutrient content claims be marketed. This intent is reflected in section 3(b)(1)(A)(viii) of the 1990 amendments.

Secondly, it is not enough to merely allow such products on the market. If these products are to be used to accomplish the purpose envisioned by Congress, they must have consumer acceptance, and they must be available for the full range of uses for which people use butter. If not, the products will quickly disappear from the market, or the uses of these products will be so limited as to have little dietary significance.

In light of these factors and of the comments that the agency received, FDA has reconsidered the proposal and concludes that it took too narrow an approach to defining the products that can appropriately include the term "butter" in their names. The comments have demonstrated that there are instances in which the minor addition of safe and suitable nondairy ingredients is necessary to reduce the fat and calories in butter products while maintaining the characteristics of butter, thereby increasing the products' consumer acceptability.

The agency notes that the use of nondairy ingredients in a dairy product like butter is not unprecedented, does not change its character, and, thus, would not mislead consumers. FDA has reviewed the dairy standards of identity in parts 131, 133, and 135 (21 CFR parts 131, 133, and 135) to determine what nondairy ingredients may be optionally added to dairy products. A number of the dairy standards provide for the use of ingredients such as flavors, emulsifiers, and stabilizers (e.g., lowfat dry milk (§ 131.123), evaporated milk (§ 131.130), skim milk (§ 131.143), and heavy cream (§ 131.150)). The standard of identity for sour cream (§ 131.160) provides for the optional use of safe and suitable ingredients that improve texture, prevent syneresis, or extend the shelf life of the product. The standard for sour cream also provides for the optional use of fruit and fruit juice and safe and suitable natural and artificial food flavoring as flavoring ingredients. Therefore, safe and suitable nondairy ingredients are already added to many types of dairy products to improve texture, add flavor, prevent syneresis, and extend shelf life, and these products remain dairy products. If these nondairy ingredients are useful in dairy products standardized in parts 131, 133, and 135, FDA believes that they may be useful in butter products.

FDA disagrees with the comment that urged FDA to allow the use of safe and suitable ingredients without restriction. The agency concludes that butter products should contain minor amounts of safe and suitable nondairy ingredients only when necessary to achieve the functions of ingredients or components of ingredients that are no longer present in the mandated quantities. As required in new § 101.67(b), the performance characteristics (e.g., physical properties, organoleptic characteristics, functional properties, and shelf life) of the butter product must be similar to those of butter. Safe and suitable ingredients added only as necessary to butter products to improve texture, add flavor, prevent syneresis, and extend shelf life will compensate for many deficiencies in performance characteristics.

The agency disagrees that it should permit safe and suitable ingredients in butter products to be consistent with the general standard in all cases. As explained in the proposal (56 FR 60523 at 60524 and 60525) and in a document entitled "Foods Standards: Requirements for Foods Named by Use of a Nutrient Content Claim and a Standardized Term" (hereinafter referred to as the general standard final rule) published elsewhere in this issue of the **Federal Register**, the legal and policy analysis of butter is different from foods standardized by regulation. Therefore, butter products are not included in § 130.10 foods but are regulated separately.

However, in § 130.10(d)(1), FDA provides for the use of safe and suitable ingredients in modified standardized foods to improve texture, add flavor, prevent syneresis, extend shelf life, improve appearance, or add sweetness so that the product is not inferior in performance characteristics to the traditional standardized food. FDA believes that the additional purposes (i.e., to improve appearance and add sweetness) for adding safe and suitable ingredients to modified foods also has application to butter products. Butter products with significantly less fat may appear more translucent than butter. Thus, ingredients to improve appearance are necessary to ensure that the product is not inferior in performance characteristics. Additionally, butter products may lack the sweetness of unsalted, sweet cream butter. Thus, ingredients to add sweetness may also be necessary to ensure that the product is not inferior in organoleptic characteristics.

Thus, FDA concludes that it is reasonable to provide for the use of safe and suitable ingredients because such use would enhance manufacturers' ability to produce butter products that perform as consumers expect. However, butter products must be made from cream or milk, or their constituents, with only those safe and suitable ingredients added as necessary to improve texture, add flavor, prevent syneresis, improve shelf life, improve appearance, and add sweetness. FDA emphasizes that butter products in compliance with new § 101.67 are dairy products, and that any addition of safe and suitable nondairy ingredients must be only in minor amounts. The addition of safe and suitable nondairy ingredients to butter products labeled under § 101.67 in excess of that which is reasonably required to achieve the performance characteristics of butter produced under 21 U.S.C. 321a constitutes deception and will be deemed to adulterate the food under section 402(b) of the act in that these ingredients are substituting for a valuable constituent. Therefore, FDA is including in new § 101.67(b) a requirement that deviations from ingredient provisions of 21 U.S.C. 321a must be the minimum necessary to achieve this effect, or the food will be deemed to be adulterated under section 402(b) of the act. The agency advises that products with nondairy ingredients in excess of these amounts fall outside of new § 101.67 and must be labeled as imitation butter if nutritionally inferior to regular butter, as butter alternatives or substitutes if not nutritionally

inferior to butter, or, if appropriate, as margarine, a margarine product, or a spread.

The agency also concludes that butter products labeled according to applicable regulations will not decrease the significance associated with the term "butter." The addition of safe and suitable ingredients must be declared in the ingredient statement as required in § 101.67(c).

FDA advises that if flavors are added to a butter product, the label must comply with § 101.22. According to § 101.22(i), if the label, labeling, or advertising of a food makes any direct or indirect representations with respect to the primary recognizable flavor, by word, vignette, or other means, or if for any other reason the manufacturer or distributor of a food wishes to designate the type of flavor in the food other than through the statement of ingredients, such flavor is considered to be the characterizing flavor. If the food contains any artificial flavor that simulates, resembles, or reinforces the characterizing flavor, under § 101.22(i), the name of the food on the principal display panel or panels of the label must be accompanied by the common or usual name of the characterizing flavor, in letters not less than one-half the height of the letters used in the name of the food. In addition, the name of the characterizing flavor must be accompanied by the word or words "artificial" or "artificially flavored," in letters not less than one-half the height of the letters in the name of the characterizing flavor.

(2) Water

8. A few comments opposed the addition of water to butter products. One comment maintained that water is not an ingredient traditionally added to butter. It stated that with current technology, the addition of water is not needed to produce a reduced fat butter, and, therefore, the addition of water to butter products should not be permitted. Another comment stated that added water would constitute a deviation from the butter standard and is not required to make an acceptable reduced fat butter product.

A number of comments stated that FDA should allow food manufacturers to add water to replace milkfat and reduce the caloric content of the product. Comments stated that water should be allowed if needed to yield an acceptable "butter" product. They stated that this might allow the development of additional products with lower saturated fat, total fat, and cholesterol. Two comments stated that the addition of water would be appropriate as long as it is clearly stated on the food label.

FDA acknowledges that the addition of water is not provided for in the statutory standard for butter, but the agency has decided to permit butter products to include ingredients that are not included in the statutory standard so that consumers may purchase such products with the characteristics of butter. There is consumer demand for products that have a significant reduction in fat and calories. Water is an ingredient that can be used to produce such a reduction as a replacement for milkfat in butter products. Although FDA agrees that with current technology, the addition of water may not always be needed to produce a reduced fat butter, the consumer may benefit from the increased reduction in saturated fat, total fat, cholesterol, and calories that can be accomplished through the addition of water. Thus, the addition of water will provide more flexibility in the formulation of butter products that may have an improved nutrition profile and may perform better than butter products formulated without any water. Therefore, FDA concludes that water may be added to butter products to replace milkfat.

Water can be added to replace milkfat in butter products in potentially very large amounts. In fact, none of the comments supporting the use of water to replace milkfat suggested any maximum level. However, to preserve the food's identity as a dairy product, the amount of water added may not exceed the amount of milk or cream ingredients. Therefore, FDA is providing in new § 101.67(a)(2) that the product may contain water to replace milkfat, although the amount of water added must be less than the amount of cream, milk, or milk constituents in the product.

The addition of water must be declared in the ingredient statement as required in § 101.67(c).

E. Minimum Dairy Ingredient Requirement

9. One comment recommended that a minimum percentage by weight of dairy ingredients (milk and its natural constituent components) be required in order to use the name "butter." The comment stated that without a minimum dairy ingredient requirement, the distinction between butter and margarine essentially vanishes. However, the comment did not recommend a specific level.

The agency disagrees with the comment. As discussed above, new § 101.67(a)(2) requires that the major ingredients in butter products be milk, cream, and derivatives of milk and cream. Because these ingredients are not generally used, or are used only in small amounts, in margarine, the distinction between the two products will be maintained. Therefore, FDA concludes that the requirement in new § 101.67(a)(2) is adequate, and that there is no need to specifically establish a minimum dairy ingredient level for butter products.

F. Nutritional Inferiority

10. One comment stated that the proposed regulation lacked specificity as to what is necessary to satisfy the requirement that the product not be nutritionally inferior. It stated that the standard for margarine (§ 166.110 (21 CFR 166.110)) specifies the required amount of vitamin A (15,000 International Units (IU) per pound) and an optional level of vitamin D (1,500 IU per pound).

The agency acknowledges that the standard for margarine designates the amount of vitamin A that must be added to margarine (§ 166.110(a)(3)) and the amount of vitamin D that may optionally be added to margarine (§ 166.100(b)). However, FDA disagrees that proposed § 101.67 lacks specificity concerning nutritional inferiority. Under proposed § 101.67(a)(3), the butter product must not be nutritionally inferior, as defined in § 101.3(e)(4), to standardized butter. This general requirement is adequate because § 101.3(e)(4) sets very specific requirements defining nutritional inferiority. The agency concludes that new § 101.67 need not specify required amounts of essential nutrients that must be added to butter products, and that no change is necessary in new § 101.67. The agency notes that general points for comparison of the nutrient values of the traditional standardized product can be found in a current valid composite data base.

G. Labeling Concerning Performance Characteristics

11. One comment recommended that the label statement be mandatory only for differences in performance characteristics that materially limit the uses of the butter product compared to the traditional standardized food that it resembles. It stated that market forces will encourage manufacturers to inform consumers about positive differences, and that consumers who select a product for its reformulated nutrient content will not be misled if they are not told about a positive change that the manufacturer believes is not sufficiently important to highlight on the product label. The comment noted that FDA

would not object if the label did not alert consumers to a minor improvement in a performance characteristic that consumers consider to be relatively unimportant for that food. In addition, the comment stated, a product may have several differences in performance characteristics, and several label statements could be confusing to consumers. The comment recommended that FDA modify proposed § 101.67(b) by limiting the labeling requirement to adverse changes that materially affect the use of the product.

The agency has been persuaded by these comments. FDA agrees that there are differences in performance characteristics that consumers may not consider important. In addition, unnecessary label statements may be confusing to consumers and may detract from other important information on the label.

Therefore, the agency is modifying new § 101.67(b) to state that:

* * * If there is a significant difference in performance characteristics that materially limits the uses of the product compared to butter, the label shall include a statement informing the consumer of such difference (e.g., if appropriate, "not recommended for baking purposes").

12. One comment noted that there is an apparent conflict in the agency's proposed requirements for the location of the disclosure of differences in performance characteristics. It stated that proposed § 101.67(b) provides that such statement must appear on the principal display panel within the bottom 30 percent of the area of the label panel; proposed § 101.67(a)(1) requires that a nutrient content claim for a butter product comply with proposed § 101.13; and proposed § 101.13(d)(1) states that if there is a difference in performance characteristics, the food may still be considered a substitute if the label includes a disclaimer adjacent to the most prominent claim. The comment requested that the final versions of proposed §§ 101.67(b) and 101.13(d)(1) be consistent. It stated that a disclosure in the bottom 30 percent of the principal display panel could easily be as prominent as, or more prominent than, a disclosure that immediately follows disclosures about the nature of the product and the reference statement. The comment stated that it is in the interest of consumers that the required disclosure of differences in performance characteristics be located in the bottom 30 percent of the principal display panel, as provided in proposed § 101.67(b). Another comment requested that FDA allow any statements concerning differences in performance characteristics to appear on any panel of the label of the product.

Under section 403(f) of the act, FDA believes that the statement informing consumers of differences in performance characteristics must appear on the label with such conspicuousness and in such terms as to render it likely to be read and understood by the consumer under customary conditions of purchase and use. The agency concludes that the statement must appear in the same area of the label as the statement of identity for the butter product so that consumers will know where to find such information. Moreover, because the statement is a material fact that helps to describe the differences between the modified food and the traditional food, it must appear in close proximity to the statement of identity. See, e.g., *United States* v. *An Article of Food * * * "Manischewitz * * * Diet Thins,"* 377 F. supp. 746, 749 (E.D. N.Y. 1974).

FDA recognizes that it inadvertently proposed in § 101.67 to require statements informing consumers of differences in performance characteristics to appear in possibly two separate locations on the label. The agency acknowledges that one statement is sufficient to inform consumers. To be consistent with the labeling of other foods, the agency concludes that the statement concerning differences in performance characteristics must appear on the label in compliance with the requirements of § 101.13(d)(1). Thus, the agency has modified new § 101.67(b) to state that the statement explaining differences in performance characteristics must appear on the label in compliance with the requirements of § 101.13(d).

13. Some comments suggested that, in order to use nutrient content claims for butter, the product must perform at least one of the principal functions of regular butter substantially as well as butter produced under section 201a of the act. Consumers can then choose to purchase the product instead of regular butter for use in that function.

FDA agrees that at a minimum, a butter product must perform at least one of the principal functions of butter substantially as well as butter as produced under 21 U.S.C. 321a. Consumers should be able to count on using a butter product in the same manner in which they use regular butter for, at the very least, one of its principal functions. To achieve this objective, FDA is requiring in § 101.67(b) that butter products must resemble butter as produced under section 201a of the act, and that differences in the performance characteristics must be clearly stated on the principal display panel of the label. In addition, the agency is adding a statement to new § 101.67(b) to require that "the modified product must perform as least one of the principal functions of butter substantially as well as butter as produced under 21 U.S.C. 321a." FDA believes that this action is necessary to ensure the minimum necessary similarity between the modified and traditional products.

H. Other Labeling

14. One comment stated that products made with nondairy ingredients should be labeled, with appropriate prominence on the principal display panel of the label, "contains nondairy ingredients."

FDA does not agree that it should require this statement on the principal display panel of the label. The agency is requiring that the major ingredients in butter products be cream, milk, or derivatives of cream or milk and is only providing for minor additions of safe and suitable ingredients (e.g., nondairy ingredients) as necessary, so that the butter product has the same characteristics as butter. Although the agency is providing for the addition of water to replace milkfat, it must not be the predominant ingredient in the product. In addition, FDA points out that new § 101.67(c)(1) requires that each of the ingredients added to the product be listed in the ingredient statement, as required by the applicable sections of part 101.

However, to further assist the consumer in differentiating between regular butter and butter products with nontraditional ingredients added, FDA is establishing a requirement in new § 101.67(c)(2) that all safe and suitable ingredients added to improve texture, prevent syneresis, add flavor, extend shelf life, improve appearance, and add sweetness and water added to replace milkfat must be appropriately identified with an asterisk in the ingredient statement. The statement "*Ingredients not in regular butter" must immediately follow the ingredient statement in the same type size. FDA is requiring similar labeling for modified standardized foods in new § 130.10, as explained in the general standard final rule.

FDA believes, however, that consumers may be misled to believe that ingredients added to restore nutrients are present in greater amounts than needed to obtain nutritional equivalency if these nutrients are identified with an asterisk in the ingredient statement. In addition, because butter has historically been a cultured product, the addition of safe and suitable bacterial cultures does not

require identification with an asterisk. Therefore, the agency is not requiring that nutrients added to restore nutrients or added safe and suitable bacterial cultures be identified by an asterisk in the ingredient statement.

15. One comment stated that the percentage of water in light butter products should be declared on the label.

FDA disagrees with the comment. As discussed above in comment 8, cream, milk, and milk constituents will be the predominant ingredients in butter products. Any water added to butter products may not be present in an amount greater than the amount of the dairy ingredients. According to § 101.4(a), all ingredients, including water, must be listed by common or usual name in descending order of predominance by weight on the label. In addition, new § 101.67(c)(2) requires that water that is added to replace milkfat must be identified with an asterisk in the ingredient statement, followed by a statement explaining that the ingredient is not in regular butter. Therefore, FDA concludes that listing water as an ingredient in this manner is adequate, and percentage labeling is not necessary.

16. One comment stated that in addition to the comparative statements allowed to appear on the label of a butter product, the label for such a product should also include a clear statement of the identity and percentage of characterizing fat or oil, for example: "Reduced Fat Butter—40% Milkfat." It stated that such a prominent statement will allow consumers to easily and readily discern the nature of the food and, thus, facilitate comparisons with other table spreads, both dairy based and vegetable based.

The agency disagrees that the additional labeling is necessary. The provisions in § 101.56(b)(3) and § 101.62(b)(4)(ii) for use of the terms "light" and "reduced fat" require that the percent reduction in fat and the identity of the reference food be declared in immediate proximity to the most prominent claim and that quantitative information comparing the fat content in the product per serving size with that of the reference food be declared adjacent to the most prominent claim or on the information panel. Under § 101.9(a), nutrition information must be provided for all butter, margarine, and substitute products. The serving size for butter, margarine, and their substitutes is one tablespoon (§ 101.12(b)). The nutrition labeling must provide information on a food product's nutrition profile, including total fat, saturated fat, and cholesterol (§ 101.9(c)(12)). In addition, information on unsaturated fat may be included in the nutrition information. The only fat ingredient permitted in butter products is milkfat, and the ingredient statement will reflect this requirement. Consumers may use this information to compare the amount of fat in butter products and margarine products. Therefore, FDA concludes that there is adequate information to inform consumers concerning the fat content of a product already required to be present on the label without requiring the additional labeling requested by the comment. However, the agency will not object if manufacturers include additional labeling to state the percentage and type of fat in the product, provided that the information is not false or misleading.

17. One comment opposed the proposed rule on the grounds that people with food sensitivities will be placed at greater risk because of difficulties of knowing what is in a product.

Section 403(i) of the act requires that all ingredients used in a food be included in the ingredient statement. Consistent with the provisions of section 403(i) of the act, FDA is including a provision in § 101.67(c)(1) that each of the ingredients used in the food must be declared on the label, as required by part 101. This requirement will ensure that consumers that have food sensitivities are informed of the presence of ingredients to which they may have allergies.

III. Conclusion

In response to comments submitted regarding the proposal for use of nutrient content claims for butter (56 FR 60523), FDA has modified proposed § 101.67. The following summarizes the changes being made to proposed § 101.67 by this final rule:

FDA has modified § 101.67(a)(2) to provide for the use of safe and suitable ingredients to improve texture, prevent syneresis, add flavor, extend shelf life, improve appearance, and add sweetness. FDA also has modified this paragraph to provide for the addition of water to replace milkfat, although the amount of water in the product must be less than the amount of cream, milk, or milk constituents.

FDA has added new § 101.67(a)(4) to require that if the product would violate section 201a of the act but for the nutrient content claim that characterizes the level of nutrients, that claim must be included as part of the common or usual name of the product.

FDA has added a statement to new § 101.67(b) to require that deviations from ingredient provisions of 21 U.S.C. 321a must be the minimum necessary to achieve similar performance characteristics as butter as produced under 21 U.S.C. 321a, or the food will be deemed to be adulterated under section 402(b) of the act.

The agency has modified § 101.67(b) by limiting the labeling requirement to changes that materially affect the use of the product.

FDA has revised § 101.67(b) to require that the mandated label statement concerning any differences in performance characteristics be in accordance with the requirements of § 101.13(d).

The agency has added a statement to new § 101.67(b) to require that the product must perform at least one of the principal functions of butter substantially as well as butter as produced under 21 U.S.C. 321a.

In new § 101.67, paragraph (c) has been redesignated as paragraph (c)(1) and new paragraph (c)(2) has been added to require that water and safe and suitable ingredients added to improve texture, prevent syneresis, add flavor, extend shelf life, improve appearance, or add sweetness shall be identified with an asterisk in the ingredient statement. The statement "*Ingredients not in regular butter" shall immediately follow the ingredient statement in the same type size.

IV. Environmental Impact

The agency previously considered the environmental effects of the action being taken in this final rule. As announced in the reproposed rule for mandatory nutrition labeling (56 FR 60366, November 27, 1991) and the proposed rule for nutrient claims (56 FR 60421, November 27, 1991), the agency determined that under 21 CFR 25.24(a)(8) and (a)(11), these actions are of a type that do not individually or cumulatively have a significant impact on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement was required.

Several comments on the proposed rule suggested that there would be significant adverse environmental effects from the final rules unless the agency allowed more time between the publication of the final rules and their effective dates. The concern in these comments was that, if the agency did not allow firms more time between the publication of the final rules and their effective dates to use up existing label inventories, large stocks of labels and labeled packaging would have to be discarded. These comments questioned whether the agency had sufficiently examined the impact of disposing of

obsolete labels and labeled packaging on this country's solid waste disposal capabilities. Two comments estimated the amounts of labeling from their respective industries, i.e., dairy and confectionery, that would need to be discarded following publication of FDA's final rules on several food labeling actions, including this action. However, these comments did not: (1) Provide details on how these estimates were derived, (2) identify what portion of the estimated amounts are attributable to these two actions, or (3) describe what impact the discarded labels and packaging would have on the disposal of solid waste. In its November 27, 1991, reproposed rule for mandatory nutrition labeling and proposed rule for nutrient content claims, the agency proposed that the final rules for these actions would become effective 6 months following their publication in the **Federal Register**.

However, the agency has decided to not make this rule effective until May 8, 1994. FDA believes there will thus be ample time for food companies to use up most of the existing labeling and packaging stocks and to incorporate labeling language that complies with FDA's regulations into their food labels. Consequently, the comments on the potential for adverse environmental effects do not affect the agency's previous determination that no significant impact on the human environment is expected and that an environmental impact statement is not required.

V. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), along with the food labeling proposals, and the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.67 is added to subpart D to read as follows:

§ 101.67 Use of nutrient content claims for butter.

(a) Claims may be made to characterize the level of nutrients, including fat, in butter if:

(1) The claim complies with the requirements of § 101.13 and with the requirements of the regulations in this subpart that define the particular nutrient content claim that is used and how it is to be presented. In determining whether a claim is appropriate, the calculation of the percent fat reduction in milkfat shall be based on the 80 percent milkfat requirement provided by the statutory standard for butter (21 U.S.C. 321a);

(2) The product contains cream or milk, including milk constituents (including, but not limited to, whey, casein, modified whey, and salts of casein), or both, with or without added salt, with or without safe and suitable colorings, with or without nutrients added to comply with paragraph (a)(3) of this section, and with or without safe and suitable bacterial cultures. The product may contain safe and suitable ingredients to improve texture, prevent syneresis, add flavor, extend shelf life, improve appearance, and add sweetness. The product may contain water to replace milkfat although the amount of water in the product shall be less than the amount of cream, milk, or milk constituents;

(3) The product is not nutritionally inferior, as defined in § 101.3(e)(4), to butter as produced under 21 U.S.C. 321a; and

(4) If the product would violate 21 U.S.C. 321a but for the nutrient content claim that characterizes the level of nutrients, that claim shall be an explicit claim that is included as part of the common or usual name of the product.

(b) Deviations from the ingredient provisions of 21 U.S.C. 321a must be the minimum necessary to achieve similar performance characteristics as butter as produced under 21 U.S.C. 321a, or the food will be deemed to be adulterated under section 402(b) of the act. The performance characteristics (e.g., physical properties, organoleptic characteristics, functional properties, shelf life) of the product shall be similar to butter as produced under 21 U.S.C. 321a. If there is a significant difference in performance characteristics (that materially limits the uses of the product compared to butter,) the label shall include a statement informing the consumer of such difference.(e.g., if appropriate, "not recommended for baking purposes"). Such statement shall comply with the requirements of § 101.13(d). The modified product shall perform at least one of the principal functions of butter substantially as well as butter as produced under 21 U.S.C. 321a.

(c)(1) Each of the ingredients used in the food shall be declared on the label as required by the applicable sections of this part.

(2) Safe and suitable ingredients added to improve texture, prevent syneresis, add flavor, extend shelf life, improve appearance, or add sweetness and water added to replace milkfat shall be identified with an asterisk in the ingredient statement. The statement "*Ingredients not in regular butter" shall immediately follow the ingredient statement in the same type size.

Dated: October 20, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

[Docket No. 91N–0343]

RIN 0905–AD08

State Enforcement Provisions of The Nutrition Labeling and Education Act of 1990

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is amending its regulations to implement section 4 of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). This section provides for State enforcement of certain requirements of the Federal Food, Drug, and Cosmetic Act (the act), so long as the State gives FDA 30 days notice of its intent to act, and certain other conditions apply. The agency is adopting regulations that will provide the States with instructions on how to give the requisite 30-day notice. FDA has framed these instructions to ensure that this notification system functions efficiently. The final rule also describes relevant State and Federal obligations.

EFFECTIVE DATE: February 5, 1993.

FOR FURTHER INFORMATION CONTACT: Janice F. Oliver, Center for Food Safety and Applied Nutrition (HFS–600), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–4187.

SUPPLEMENTARY INFORMATION:

I. Background

In response to the requirements of the 1990 amendments (Pub. L. 101–535), FDA published in the **Federal Register** of November 27, 1991 (56 FR 60534), a proposal to implement section 4 of those amendments. Section 4 amended section 307 of the act (21 U.S.C. 337) to provide for State enforcement of certain requirements of the act, so long as the State provides 30 days notice of its intent to act, and certain other conditions apply. The agency proposed to adopt regulations that would provide the States with instructions on how to give the requisite 30-day notice and to describe relevant State and Federal obligations. Interested persons were given until February 25, 1992, to comment.

FDA received approximately 24 responses to this proposal, each containing one or more comments, from trade associations, government organizations, individual States, food manufacturers, consumers, and consumer groups. The comments generally supported the proposal. Several comments addressed issues outside the scope of the proposal (e.g., delaying implementation of the regulations and delaying enforcement of the regulations) that will not be discussed here. A number of comments disagreed with various aspects of the proposal. These comments suggested modification and revision of various provisions of the proposal. A summary of these comments and the comments' suggested changes, along with the agency's responses, follows.

II. State Enforcement Provisions of the 1990 Amendments

A. Informal Enforcement Actions

In proposed § 100.2(j), FDA defined "informal enforcement actions," a term that is used in section 307(b)(2)(B) and (C) of the act, and defined in the agency's proposed implementing regulations, to include warning letters, recalls, and detentions as well as other administrative actions.

1. One comment suggested that FDA remove detentions as a type of informal enforcement action because FDA has no detention authority for foods.

The use of the word "detentions" in the proposal refers to detentions of imports under the provisions of section 801 of the act (21 U.S.C. 381) and detentions authorized under the provisions of the Federal Meat Inspection Act (FMIA), the Poultry Products Inspection Act (PPIA), and the Egg Products Inspection Act (EPIA). The agency is authorized to detain imported food products if it appears that the products have been manufactured, processed, or packaged under insanitary conditions, or that the products are adulterated or misbranded, under the act. The agency also is authorized to detain meat, poultry, and egg products if they are found outside a plant inspected by the U.S. Department of Agriculture, and the agency has reason to believe that the products are adulterated or misbranded, under 21 U.S.C. 467f(b), 679(b), and 1052(d). Import detentions and detentions under the FMIA, PPIA, and EPIA are all administrative enforcement actions, and, therefore, informal actions under proposed § 100.2(i)(1). Consequently, the agency concludes that no change in the regulation in response to this comment is necessary.

2. Another comment suggested that FDA remove warning letters as a type of informal enforcement action. This comment stated that the agency often issues warning letters when no further action is planned by FDA, and that no response stating that corrections have been made is required from the recipient.

FDA disagrees with this comment. Warning letters are used by the agency to notify a firm that it is not in compliance with the act or with agency regulations, that failure to correct these violations may result in formal enforcement actions by FDA, and that a reply with a full statement of all corrections that have been or will be made is required within 10 days. A study of warning letters by FDA revealed that approximately 93 percent of the warning letters issued by FDA elicit a response from the recipient. Because of these facts, FDA continues to believe that it is appropriate to include warning letters as a type of informal enforcement action in the final rule. If the firm does not respond to the warning letter within the time provided in the warning letter, and the agency does not take any further action, the State will be free to act after 90 days under section 307(b)(2)(B) of the act.

3. Two comments suggested that adverse publicity be included as a type of informal enforcement action because FDA has the authority to issue publicity under section 705 of the act (21 U.S.C. 375). The agency acknowledges that it has the authority to issue publicity under section 705 of the act. The authority is conferred to the agency in situations involving imminent danger to health or gross deception of the consumer. However, the agency does not believe that it is necessary to specifically list publicity as a type of informal enforcement action in the final rule below. This type of action is included among the "other administrative enforcement actions" that are listed in proposed § 100.2(j)(1).

4. Several comments expressed concern that informal enforcement actions taken by FDA will preclude formal enforcement actions that could be taken by the State. One of these comments said there was no indication in the 1990 amendments that Congress intended the States to be preempted by anything other than formal action by FDA. Several comments wanted FDA to clarify that State and local enforcement mechanisms remain unaffected by the 1990 amendments.

Section 307(b)(2)(C) of the act states that no proceedings for the civil enforcement, or to restrain violations, of certain enumerated sections of the act may be commenced by a State if FDA has settled an informal or formal enforcement action against that food. Thus, contrary to what at least one

comment asserted, State action can be precluded by informal FDA action. Section 307 of the act, however, only applies to actions by a State to enforce certain sections of the act. Nothing in this section would preclude a State from taking action against a particular food under its own State law, even if FDA has commenced or settled an enforcement action against that food.

B. State Intervention in Criminal Proceedings

5. Several comments expressed concern that proposed § 100.2 would permit States to intervene as a matter of right in Federal criminal proceedings. The comments stated that no criminal authority was conferred upon the States by section 307(b)(1) of the act.

In response to these comments, FDA reconsidered whether to include criminal proceedings among the formal enforcement actions listed in proposed § 100.2(j)(2). While section 307(b) of the act is not clear on its face as to whether a pending criminal proceeding would, under section 307(b)(2)(B) or (C) of the act, preclude State action, there is nothing in the act to require the agency to hold that it would.

Therefore, FDA has decided to reverse the position that it tentatively took in the proposal. FDA is striking criminal actions from the list of formal enforcement actions in proposed § 100.2(j). FDA is revising this section to include only civil judicial enforcement action. As a result, § 100.2(j)(2) is coextensive with section 307(b)(1) of the act. A second result of this change will be that a pending Federal criminal action that arises out of a misbranding under the sections listed in section 307(b)(1) of the act will not serve to preclude a State from bringing a civil action under the act in Federal court against the underlying misbranding.

C. Agency Action Barring State Action Against Food in Federal Court

6. Several comments discussed the agency's statement that an agency action anywhere in the United States against the food in question would, under section 307(b)(2) of the act, bar a State action against the same food in Federal court. The majority of the comments agreed with this statement. One of the comments said that this preclusive effect should not be limited to FDA actions. This comment said that an action by a State to enforce the Federal law against a food within its jurisdiction precludes a second enforcement proceeding by another State or by FDA against the same food. The comment also said that if the States can enforce identical State regulations in the State courts, such actions should preclude an FDA action in the same State. Another comment, objecting to the agency's interpretation of the preemptive provisions of the 1990 amendments, argued that a State's action should be preempted only in cases where the FDA action will result in the discontinuation of the illegal practice in that State and in the nation. Finally, one comment requested that FDA revise proposed § 100.2 to provide that if the agency, upon notification by the State under section 307(b)(2) of the act, advises a State not to proceed, that State may not thereafter independently initiate enforcement proceedings based upon the same violations in State court under an identical State law.

The agency agrees in part with these comments. The enforcement actions available to the States under the provisions of section 307 of the act are seizure and injunction. The agency agrees that if FDA or a State brought a seizure action against a particular misbranding violation, the action would have a preclusive effect on another State or FDA. Section 304 of the act prohibits multiple seizures based on the same alleged misbranding of food. In light of the changes in section 307 of the act, who brings the first action, whether it is FDA or a State, would not be significant for the purposes of section 304 of the act. The first action filed would preclude any others.

In the case of an injunction, however, there is nothing in the act that limits the number of such actions that can be brought. Therefore, while an FDA injunction action would preclude State enforcement actions under the act for at least 90 days under section 307(b)(2), such action by a State would have no effect on FDA's or another State's ability to bring an action. However, the agency also notes that particularly in this time of limited government resources, it is highly unlikely that any jurisdiction would bring a duplicative injunction action.

The agency does not agree that a State action to enforce a State law that is identical to the act against food in its own jurisdiction precludes an FDA action based on the same violation. Section 307 of the act applies only to proceedings to enforce the act. State law cannot act to preempt Federal law or to preclude Federal action. Conversely, the act does not give FDA the authority to preclude a State from enforcing an identical State law. If FDA advises a State that the agency is commencing or has settled an enforcement action or proceeding, then the State is precluded from bringing an action under the act in Federal court. The act does not prohibit a State from enforcing an identical State law. Nonetheless, FDA intends to work with the States to attempt to ensure that State provisions that are identical to provisions in the act are interpreted by the States in a way that is as consistent as possible with FDA's interpretation of the Federal provisions.

D. State Notification Letter

7. Several comments wanted States to provide FDA with evidence supporting the proposed action. The comments said that FDA should require the same evidence from a State that it requires from one of its district offices when reviewing proposed enforcement actions. These comments also wanted a State to inform FDA of the type of enforcement action that it expects to bring. On the other hand, one comment said that FDA was requiring too much information from States, and that the information that FDA is seeking may not be available at the beginning of an investigation. The comment stated that the 1990 amendments only require that a State give notice to FDA that it intends to bring an action, and that the detailed information being asked for by FDA would needlessly delay State enforcement action where an FDA action may not even be contemplated.

FDA stated in the preamble to the proposed regulation that it wanted the States to inform it of the type of action that they planned to take (56 FR 60534 at 60535). FDA included this provision as part of a parenthetical statement in the proposed format in § 100.2(d) (i.e., "name of products covered by the notification and the enforcement action that is to be initiated"). In view of the comments, and to eliminate any possible confusion, the agency is revising proposed § 100.2(d) to include in the format for the State's notification specific provision under item I., "Type of Enforcement Action," for the State to inform FDA of the type of action it is planning to take.

The agency disagrees with the suggestion that it require more specific information as part of the State notification, including a description of the evidence that the State is relying on to support its action. The agency considered the need for States to submit evidence to support the proposed action. However, the factors that FDA will consider in reviewing State notices of their intent to enforce certain sections of the act bear on different concerns than those that the agency considers in reviewing a recommendation from a district office.

When a district recommendation for an enforcement action is reviewed within the agency, there is a great deal

of concern about the merits of the case. A decision must be made as to whether to commit the agency's resources to prosecuting it. In reviewing a State notice of intent, FDA is not responding to the merits or strengths of the State's proposed action. The agency is only trying to determine whether FDA has taken, is taking, or, in the near future, is likely to take action. The States may proceed if FDA has not commenced or settled an action. It is up to the courts to decide the merits of the State's case. The information that the agency is asking a State to submit as part of its notification is the information that is necessary to ensure that the State and FDA are not duplicating efforts. Thus, FDA rejects the suggestion that it require the same information from a State as from its district offices.

The agency also disagrees with the request that the agency limit the information necessary in a notice. The comment suggested that the notice should be limited to only the names of the State and of the official giving notice, the name of the product involved, a copy of the label involved, when appropriate, and the alleged violation of the act. Although the 1990 amendments only require that the State give notice to the agency that it intends to bring an action, the information that the agency is asking the State to include in the notification letter is the information that is necessary if the agency is to provide a timely response to the State's notice.

The purpose of section 4 of the 1990 amendments is to provide a role for State enforcement of Federal statutory provisions that have preemptive effect. (See 136 Congressional Record H5840 (July 30, 1990)). However, such a role requires close coordination between State and Federal officials. The agency believes that it is requesting the minimum amount of information that is necessary to ensure that such close coordination exists. As mentioned above, the types of action that are available to the States for the enforcement of the act under the provisions of section 307 of the act are seizure and injunction. The agency would expect that a State would normally have the information requested in proposed § 100.2(d) before it could initiate these types of actions. Thus, the agency does not believe that compiling the information that it is requesting in proposed § 100.2 will delay State action.

However, the agency has reconsidered the provisions for the State notice in light of this comment and has determined that format items E and F are redundant. Moreover, the agency recognizes that there may be situations, such as in the case of a seizure of misbranded food, where the identity of the responsible firm cannot be readily determined. Thus, the agency is modifying the format for the notice by deleting item F and revising item E to read "Name and Address of firm believed to be responsible for violations."

E. Response to State Notification Letter

8. Several comments disagreed with proposed § 100.2(h) that provided that the Director of the Division of Regulatory Guidance in the Office of Compliance at the Center for Food Safety and Applied Nutrition, FDA, will respond to the State notification letter. The comments suggested that the agency follow its existing procedures for formal enforcement actions under which such actions are taken with the concurrence of the Director of the Office of Compliance and the Chief Counsel along with review by the Office of Enforcement.

The agency disagrees with these comments. These comments do not correctly characterize the action that occurs as a result of the submission of a State notification. FDA's response to such a letter simply informs the State of action that FDA has taken or is taking, and it is not an evaluation of the merits of the State's case. The Division of Regulatory Guidance is the central focus within FDA for all enforcement actions regarding food. Thus, the agency concludes that it is appropriate that this division be given authority to inform a State whether Federal action is being taken concerning a particular product or firm.

9. Several comments stated that the relationship between the State and FDA once the State notification letter is submitted is not well understood.

Once a State has notified the agency of its intent to bring an action, FDA believes that it is incumbent on the agency to inform the State whether it (FDA) has commenced an informal or formal action pertaining to the food in question within 30 days of the State notification. FDA has reflected this obligation in proposed § 100.2(h). If FDA advises a State that the agency has commenced an informal or formal action, under section 307(b)(2)(B) of the act, the State must wait a total of 90 days before it can commence an action. FDA will also advise the State if the agency has not commenced an informal or formal action, in which case the State may proceed with its proposed action. FDA must either have an informal or formal action pending or begin such an action within 30 days of the State's initial notice, for the State to be precluded from taking the enforcement action. FDA will maintain communication with the State regarding the resolution of enforcement actions.

10. One comment requested that FDA clarify that once a State has begun an enforcement action against a particular product, "no new notice is required to add defendants to the State action where these defendants are involved in the same scheme or where these defendants are acting or participating with other defendants to sell the same product."

The question raised by the comment is too general for the agency to provide specific clarification. The agency notes that it would generally agree that the simple addition of a corporate officer as a defendant or of an additional lot of a product in an action addressing a specific violation of the act would not require a new notice. However, the extension of an action to include new corporate entities or differing products would likely require a new notice. The agency believes that proposed § 100.2(a) is sufficiently clear on this point that there is no need to revise the regulations.

F. Public Disclosure

11. One comment requested that FDA publicly disclose information contained in State notification letters, excluding trade secrets and confidential information. Several comments wanted public disclosure of information contained in FDA's response to State notification letters.

The agency believes that proposed § 100.2(i), regarding exemption from public disclosure of information in State notification letters, is appropriate. Section 20.61 of FDA's regulations (21 CFR 20.61) provides that trade secret and confidential commercial information is not available for public disclosure. Section 20.64 of FDA's regulations (21 CFR 20.64) provides that an investigatory record for law enforcement purposes may be withheld by the agency from public disclosure if disclosure of the record would interfere with enforcement proceedings and disclose investigative techniques and procedures. The State notification letter is an investigatory record in that it relates to a potential regulatory enforcement action. Such an investigatory record is available for public disclosure as provided in § 20.64(c) and (d).

Section 20.88 (21 CFR 20.88) provides that investigatory records compiled for law enforcement officials who perform counterpart functions to FDA at the State and local level are exempt from

public disclosure pursuant to § 20.64. The agency's response to a State notification letter is not available for public disclosure as provided by § § 20.64 and 20.88.

G. Preemption and Enforcement

12. Several comments expressed concern that a State could enforce a State law that is identical to a section of the act but have an interpretation of the law that is different from FDA's interpretation of the act.

FDA realizes that it is possible for State laws that are identical to Federal laws to be interpreted differently by the different States. As discussed above, the agency believes that close cooperation between FDA and the States will ensure that goals of uniformity are met while still addressing the concerns of the citizens of a State.

H. FDA's Authority to Interpret the Act

In the preamble to the proposed regulations the agency stated that to avoid any suggestion of an unconstitutional delegation to States to enforce the act, FDA retains full authority to advise States of what FDA believes is the proper interpretation of any of the sections of the act that they may seek to enforce. The agency stated that if FDA advises a State that its proposed action is inconsistent with FDA's interpretation, section 307 of the act requires that the State conform its interpretation to FDA's (56 FR 60534 at 60535 to 60536).

13. Several comments agreed, and one comment disagreed, with this agency statement. One comment wanted the final rule to add a new § 100.2(h)(3) that would require the agency to advise the States that the interpretation of the act that they seek to enforce is inconsistent with FDA's interpretation, that the labeling in question does not violate the act, and that they may not bring an enforcement proceeding. The comment that disagreed said that it is up to the courts to decide the ultimate meaning of the provisions of the act in disagreements between the States and FDA.

As stated above, FDA generally will not be issuing an interpretation to the State of the Federal requirements when it responds to a State notification letter. It will merely inform the State that the agency has commenced or settled an informal or formal enforcement action or is prosecuting or has settled a court proceeding, or has done none of these things. Therefore, the final rule does not need to include a section to require the agency to advise a State that its interpretation is inconsistent with FDA's. However, after consideration of the comments, the agency continues to believe that the position that it enunciated in the proposal is correct for the reasons that it presented (see 56 FR 60534 at 60535 to 60536). Therefore, FDA reserves the right to advise a State that its proposed action is inconsistent with FDA's interpretation of the act and will do so as circumstances warrant.

14. Several comments wanted the agency to ensure that a mechanism was available to provide the States with agency interpretations. These comments wanted FDA to impose time limits upon itself to issue interpretations.

Whenever a State would like an interpretation of the act, it may seek an advisory opinion under § 10.85 (21 CFR 10.85). FDA will respond to the request in a timely manner. The agency's Division of Federal-State Relations also will work closely with the States to ensure that FDA's interpretations of the act and the agency's regulations on food labeling are made available to the States. The State Training Branch of FDA's Office of Regulatory Affairs will conduct training classes for the States after implementation of the final regulations.

15. One comment recommended that the agency consider establishing an advisory panel of State and local officials to assist FDA in the development of interpretations.

FDA is charged by Congress to enforce requirements of the act. Therefore, FDA believes that as a general matter, it is its responsibility to interpret the act. However, the agency also recognizes the value of receiving input from State and local officials as well as others in the development of its interpretations. To this end the agency is establishing a Food Advisory Committee that will consider a broad range of questions concerning food (57 FR 8128, March 6, 1992). FDA will be including representatives from State and local governments on this committee. The agency notes that it utilizes a number of other approaches to ensure that it is aware of State and local government concerns, including participation in activities of the Association of Food and Drug Officials and regular contacts with the State through FDA's Division of Federal-State Relations. Thus, FDA does not believe that it is necessary to establish a separate standing advisory panel of State and local officials as a regular part of FDA's process of interpreting the act.

III. Conclusion

FDA is revising proposed § 100.2(d) in response to comments submitted regarding the proposal on the State enforcement provisions of the 1990 amendments (56 FR 60534). FDA has revised proposed § 100.2(d), regarding the State notification letter format, by modifying the format item E to read "E. Name and address of firm believed to be responsible for violations," deleting item F, renumbering items G, H, and I as F, G, and H, and including a new format item I to read "I. Type of enforcement action." FDA has also modified proposed § 100.2(j)(2) to read: "formal enforcement actions" include seizures, injunctions, or other civil judicial enforcement actions that pertain to the food in question." The agency has adopted the remainder of the provisions of § 100.2 as proposed with only minor editorial revisions because the agency did not receive any comments concerning them, or because, as discussed above, the comments that it did receive did not justify a change.

IV. Economic Impact

In its November 1991 proposal, FDA concluded that the proposed requirements did not constitute a major rule and that no significant impact on a substantial number of small entities, including small business, would derive from this action. FDA has not received any new information or comments on the proposal that would alter its previous determination.

V. Paperwork Reduction

Section 100.2 of this final rule contains notification requirements that were submitted for review and approval to the Director of the Office of Management and Budget (OMB), as required by section 3504(h) of the Paperwork Reduction Act of 1980. The requirements were approved and assigned OMB control number 0910–0275.

List of Subjects in 21 CFR Part 100

Administrative practice and procedure, Food labeling, Foods.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 100 is amended as follows:

PART 100—GENERAL

1. The authority citation for 21 CFR part 100 continues to read as follows:

Authority: Secs. 201, 301, 307, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 337, 342, 343, 348, 371).

2. Section 100.2 is added to subpart A to read as follows:

§ 100.2 State enforcement of Federal regulations.

(a) Under section 307 of the Federal Food, Drug, and Cosmetic Act (the act),

a State may bring, in its own name and within its own jurisdiction, proceedings for the civil enforcement, or to restrain violations, of sections 401, 403(b), 403(c), 403(d), 403(e), 403(f), 403(g), 403(h), 403(i), 403(k), 403(q), or 403(r) of the act if the food that is the subject of the proceedings is located in the State.

(b) No proceeding may be commenced by a State under paragraph (a) of this section:

(1) Before 30 days after the State has given notice to the Food and Drug Administration (FDA) that the State intends to bring such proceeding.

(2) Before 90 days after the State has given notice to FDA of such intent if FDA has, within such 30 days, commenced an informal or formal enforcement action pertaining to the food which would be the subject of such proceeding.

(3) If FDA is diligently prosecuting a proceeding in court pertaining to such food, has settled such proceeding, or has settled the informal or formal enforcement action pertaining to such food.

(c) A State may intervene as a matter of right, in any court proceeding described in paragraph (b)(3) of this section.

(d) The notification that a State submits in accordance with paragraph (b) of this section should include the following information and be submitted in the following recommended format:

———————

(Date)
Name of State agency ————————
Post office address ————————
Street address ————————
City, State, and ZIP code ————————
Name of product(s) covered by the notification ————————
Reporting official, title, and telephone no. ————————
FAX No. ————————
Agency contact (if different from reporting official), title, and telephone no. ————————

Director,
Division of Regulatory Guidance (HFF–310),
Center for Food Safety and Applied Nutrition,
Food and Drug Administration,
200 C St. SW.,
Washington, DC 20204.

To Whom It May Concern:

The undersigned, ———, submits this letter of notification pursuant to section 307(b)(1) of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 337(b)(1)) with respect to ————. (name of products covered by the notification and the enforcement action that is to be initiated)

Attached hereto, and constituting a part of this letter of notification are the following:

A. The name of the product.

B. The type and size of each product container.

C. Copy of the label and labeling of the product.

D. Manufacturing code (if applicable).

E. Name and address of firm believed to be responsible for violations.

F. Name and address of parent firm (if known).

G. Reason for the anticipated State enforcement action (list specific violations, including sections of the law violated).

H. Name of firm against which action is anticipated (if applicable).

I. Type of enforcement action.

Yours very truly,
Reporting Agency
By ————————
(Indicate authority)

(e) The letter of notification should be signed by a State official authorized by the State to institute the contemplated enforcement actions.

(f) The letter of notification should be sent to the Division of Regulatory Guidance (HFF–310), Center for Food Safety and Applied Nutrition, Food and Drug Administration, 200 C St. SW., Washington, DC 20204, FAX number 202–205–4642.

(g) FDA will notify the State of the date in which its letter of notification was received by FDA, Center for Food Safety and Applied Nutrition, Division of Regulatory Guidance (HFF–310) (within 2 working days after date of receipt). This date will be the date of notification for the purposes of paragraph (b) of this section.

(h) The Director, Division of Regulatory Guidance, Office of Compliance, Center for Food Safety and Applied Nutrition, FDA, will respond to the State's notification within 30 days of the date of notification by advising:

(1) Whether FDA has commenced an informal or formal enforcement action pertaining to the food that is the subject of the notification; or

(2) Whether FDA is prosecuting a proceeding in court pertaining to such food, has settled such proceeding, or has settled informal or formal enforcement action pertaining to such food.

(i) Information contained in State notification letters shall be exempt from public disclosure to the same extent to which such information would be so exempt pursuant to §§ 20.61, 20.64, and 20.88 of this chapter.

(j) *Definitions.* (1) "Informal enforcement actions" include warning letters, recalls, detentions, or other administrative enforcement actions that pertain to the food in question.

(2) "Formal enforcement actions" include seizures, injunctions, or other civil judicial enforcement actions that pertain to the food in question.

(Information collection requirements in this section were approved by the Office of Management and Budget (OMB) and assigned OMB control number 0910–0275.)

Dated: October 20, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

[Docket No. 91N–0038]

RIN 0905–AD08

State Petitions Requesting Exemption from Federal Preemption

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is amending its regulations to provide for petitions requesting exemption from preemption for State or local food standards and for certain other State or local labeling requirements that are preempted under the provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments). The regulations set out the procedures for the submission, and for agency review, of these petitions and the information that the petitioner should supply. Petitions by State and local governments seeking exemption from specified preemptive Federal requirements are specifically authorized by the 1990 amendments.

EFFECTIVE DATE: February 5, 1993.

FOR FURTHER INFORMATION CONTACT: Elizabeth J. Campbell, Center for Food Safety and Applied Nutrition (HFS–155), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–5229.

SUPPLEMENTARY INFORMATION:

I. Background

In response to requirements of the 1990 amendments (Pub. L. 101–535), FDA published in the **Federal Register** of November 27, 1991 (56 FR 60528), a proposal to provide for petitions requesting exemption from preemption for State or local food standards and for certain other State or local labeling requirements that are preempted under the provisions of the 1990 amendments. The proposed regulations set out the procedures for the submission, and for agency review, of these petitions and the information that the petitioner should supply. Interested persons were given until February 25, 1992, to comment.

FDA received over 50 letters, each containing one or more comments, from industry, trade associations, States, government organizations, consumer organizations, a Congressman, and a consumer. The comments generally supported the proposal. Several letters submitted in response to the proposal addressed issues outside the scope of the proposal and will not be discussed here. A number of comments disagreed with, and requested clarification of, various aspects of the 1990 amendments or the proposal. Some of these comments suggested modification and revision in various provisions of the proposal. A summary of the comments and the agency's responses follow.

II. General Comments

1. One comment asserted that individuals should have the right to petition for exemption. The comment stated that this would allow for a more universally equitable resolution of preemption issues.

Only States and political subdivisions of States have legal standing to petition for exemption. Section 403A(b) of the Federal Food, Drug, and Cosmetic Act (the act) (21 U.S.C. 343–1(b)) provides only that upon the petition of a State or a political subdivision of a State, the Secretary may exempt a State or local requirement from the effect of section 403A(a) of the act. Thus, Congress did not provide for petitions from other parties, and the agency has no authority to grant the comment's request.

2. Some comments wanted to know if State requirements were preempted when the products in question were strictly intrastate products.

The agency advises that under section 403A(a) of the act, State requirements are not subject to preemption to the extent that they apply to intrastate products.

III. What State Laws Are Covered

A. "Not Identical To"

3. One comment suggested that whether a State or political subdivision of a State needs to seek exemption from preemption for a law or regulation should be based on whether there are substantive differences between the State and the Federal requirements.

The agency does not accept the comment. While the results under the comment's suggested test might be the same as under the agency's proposal, FDA believes its proposal is more consistent with the statutory test. Under § 100.1(c)(4), if the State requirement is identical to the Federal law, it is not subject to preemption under section 403A(a) of the act. In addition, if the State requirement does the same thing that the Federal law does, even if the words are not the same, then it is effectively the same requirement as the Federal requirement. FDA's view, as embodied in § 100.1(c)(4), is that such a State or local requirement need not be preempted, and that there is consequently no need to exempt it from preemption. Therefore, the only State requirements that are subject to preemption are those that are affirmatively different on matters that are covered by section 403A(a) of the act.

A State will only petition for exemption of a requirement from preemption if the requirement is, or the State has a good reason to believe that it is, subject to preemption. The agency believes that the petition process that it is establishing provides States with an appropriate mechanism for requesting such an exemption from preemption. If a State can adequately demonstrate the need for the labeling requirement, that such requirement will not cause a food to be in violation of Federal law, and that it will not unduly burden interstate commerce, then FDA will propose to grant the exemption.

B. More Stringent State Requirements

4. Several comments expressed concern that stringent State laws may be preempted by less restrictive Federal regulations. These comments said that States should retain the authority to enforce strict State laws that serve the needs of its citizens. One of the comments was concerned that its regulation pertaining to open dating for perishable and semiperishable food products would be preempted, and it would be precluded from enforcing these open-dating provisions. Another comment said that producers who are able to successfully differentiate their products based on superior quality should not be prevented by Federal law from marketing that product under a State standard that rewards that quality.

FDA acknowledges that some stringent State laws will be preempted by less restrictive Federal regulations. However, one of the goals of the 1990 amendments is national uniformity in certain aspects of food labeling, so that the food industry can market its products efficiently in all 50 States in a cost-effective manner (Statement of Rep. Madigan, 136 Congressional Record H12954, October 26, 1990). Thus, in enacting the 1990 amendments, Congress decided that even though Federal requirements may preempt more restrictive State requirements in certain instances, the net benefits from national uniformity in these aspects of the food label outweigh the loss in consumer protection that may occur as a result. In regard to open dating, the agency notes that State laws and regulations will not be preempted because FDA does not have authority to establish such requirements under the

sections of the act that have been given preemptive effect. Therefore, a State will not be precluded from enforcing its open-dating provisions. With respect to the latter comment, the agency advises that producers who choose to market a superior quality product are not precluded by Federal preemption from doing so.

In response to inquiries from State officials and food producers concerned about the consequences of the preemption provisions, FDA has informed them that while the agency may act in the future to remove from its regulations any provisions that permit more stringent State requirements, those provisions remain in place for the moment and presumably have the force and effect of law. FDA does not intend to interfere with actions by States to enforce their standards based on existing regulations.

C. State Common or Usual Name Regulations

5. Several comments questioned whether a State common or usual name regulation was preempted if the regulation was promulgated in conformance with § 102.5 *General principles* (21 CFR 102.5), and it is a food for which FDA has not adopted a common or usual name as a standard.

Section 403(i)(1) of the act, which requires that the label of a food bear its common or usual name, if any, is one of six misbranding sections of the act identified in section 403A(a)(3) of the act that were the subject of a study mandated by section 6(b) of the 1990 amendments. The purpose of the study was to determine which of the six sections are adequately being implemented by FDA regulations and which are not. The agency contracted with the National Academy of Sciences, Institute of Medicine (IOM) to conduct the study.

On July 28, 1992 (57 FR 33283), as required by the 1990 amendments, the agency published its proposed lists of those sections that are adequately being implemented and those sections that are not. Based on the IOM's recommendations, the agency tentatively concluded that FDA regulations in part 102 (21 CFR part 102) adequately establish procedures for the development and application of common or usual names under section 403(i)(1) of the act.

The agency is publishing elsewhere in this issue of the **Federal Register** a final rule entitled, "Certain Misbranding Sections of the Federal Food, Drug, and Cosmetic Act That Are, and That Are Not, Adequately Being Implemented by Regulation Notice of Final Lists." Based upon FDA's evaluation of the recommendations of the IOM, its consideration of the comments on the proposed lists, and other available information, the agency provides in that final rule its finding that section 403(i)(1) of the act is being adequately implemented.

Section 6(b)(3)(B) of the 1990 amendments provides that "With respect to a section which is found by the Secretary to be adequately implemented, no State or political subdivision of a State may establish or continue in effect as to any food in interstate commerce any requirement which is not identical to such section." Thus, a State common or usual name regulation promulgated in conformance with § 102.5 for a food for which there is no specific Federal common or usual name regulation is preempted. However, the agency would consider an exemption for preemption based on the conditions that led the State to believe that there was a need for the State common or usual name regulation.

D. State Standards of Identity, Quality, or Fill Regulations

6. Several comments asked whether a State standard of identity, quality, or fill is preempted if it is for a food for which there are no Federal standards.

Under section 403A(a)(1) of the act, a State may not establish or continue in effect a standard of identity, quality, or fill for a food that is the subject of a standard of identity under section 401 of the act (21 U.S.C. 341) that is not identical to the Federal standard. If there is no Federal standard of identity, quality, or fill for a particular food, then there is no basis, under the terms of section 403A(a)(1) of the act, for finding that there is Federal preemption. By contrast, under section 403A(a)(2) through (a)(5) a State may not establish or continue in effect any requirement "of the type" set forth in the sections of the act specified in section 403A(a)(2) through (a)(5). Thus, State or local requirements can be preempted under section 403A(a)(2) through (a)(5) even if no analogous Federal regulation had been promulgated.

7. A comment noted that there was a typographical error in proposed § 100.1(c)(4) in that the word "quantity" should be "quality" instead.

The agency acknowledges the typographical error, and it has replaced the word "quantity" with the word "quality" in § 100.1(c)(4) set forth below.

E. State Laws Adopted from the U.S. Department of Commerce Handbook

8. Two comments asked if the weights and measures standards for food products adopted by States from U.S. Department of Commerce publications, contained in the National Institute of Standards and Technology (NIST) Handbook 130 1992 (Uniform Packaging and Labeling Regulation and the Uniform Regulation for the Method of Sale of Commodities) and the NIST Handbook 133 (Checking the Net Contents of Packaged Goods), would be preempted under the 1990 amendments. The comments said that the requirements of these publications do not appear to be different than those in § 101.105 *Declaration of net quantity of contents when exempt* (21 CFR 101.105) but do go into more detail. The comments asked if FDA would adopt these U.S. Department of Commerce publications as part of its regulations.

The agency advises that State requirements adopting U.S. Department of Commerce publications would not be subject to preemption if the State requirements can be considered to be identical to § 101.105. FDA's view, as reflected in § 100.1(c)(4), is that the fact that the State requirements contain more detail than found in the Federal regulation does not necessarily mean that the State requirements would be subject to preemption. Preemption would occur only if the detailed information included in the State requirements imposes different or stricter requirements than provided for in § 101.105.

To resolve any concerns that a State may have about a potential conflict between its requirement and a Federal requirement, a State may petition the agency for exemption from preemption for its requirement. If FDA concludes that the State requirement is identical to the Federal requirement, the agency will advise the State of that fact and deny the State's petition without prejudice. While the agency's opinion is not binding, it will, if a question of preemption with regard to that State requirement is raised in court, provide evidence that the State requirement, in FDA's view, is not preempted. If the court later decides otherwise, the State still has the option of petitioning FDA for an exemption from preemption.

FDA is not adopting the U.S. Department of Commerce publications as part of its regulations at this time. However, because the issues surrounding the harmonization of FDA's regulations and the U.S. Department of Commerce publications that have been adopted and enforced by States are bot-

important and complex, the agency would welcome a meeting with the National Conference on Weights and Measures, State officials, and other interested Federal agencies to decide what steps are necessary and appropriate to ensure that FDA's regulations and the relevant Department of Commerce publications are harmonized.

9. A comment asked whether all the States that had adopted regulations identical to those the Department of Commerce publications had to petition for exemption, or whether FDA could issue a blanket exemption for all of those States.

The agency advises that it will accept blanket exemption petitions that cover circumstances such as those represented by the example of the State regulations adopted in response to the U.S. Department of Commerce's publications. If, because of the detailed information from such publications that is included in the States' requirements, the States consider their regulations to be subject to preemption, one or more States should submit an exemption petition that meets the requirements set forth below in § 100.1. Among other things, the exemption petition would need to show the authority for the petitioner to act on behalf of the other States or political subdivisions of the States, identify the State requirements and the dates that they were enacted, and include a statement of the grounds upon which the petition is based. Depending upon the circumstances, the agency will consider granting an exemption from preemption for the requirements of each of the States or political subdivisions covered by the petition.

IV. State Petitions

A. General

10. Several comments objected to the statutory provision that allows a State to petition for an exemption from preemption by Federal food labeling regulations. These comments were of the view that all State laws regarding food labeling should be preempted by Federal food labeling regulations, and that States should not be allowed to petition for an exemption. On the other hand, another comment said that State laws regarding food labeling should not be preempted by Federal regulation, and thus there is no need for a process to petition for an exemption.

Section 403A(b) of the act specifically allows a State, or a political subdivision of a State, to petition the Secretary for an exemption from preemption. It states that the Secretary may, upon being petitioned by a State, or political subdivision of a State, exempt any State or local requirement that: (1) Would not cause any food to be in violation of any applicable requirement under Federal law, (2) would not unduly burden interstate commerce, and (3) is designed to address a need for information that is not met by the misbranding sections of the act referred to in section 403A(a) of the act. Given this provision, the agency has concluded that the procedures that it is establishing for the submission and consideration of petitions for exemption from preemption are necessary to effectuate the law. Therefore, the agency rejects the comments on this point.

B. Use of Medical Device Amendments as a Model

11. One comment suggested that FDA model its regulations on State petitions for exemption from preemption under the 1990 amendments after FDA's medical device regulations for such exemptions (21 CFR 808.20, 808.25, and 808.35) rather than after the Consumer Product Safety Commission (CPSC) regulations. The comment asserted that the medical device regulations are better suited as a model because they are more comprehensive than the CPSC regulations. The comment noted that the medical device regulations require States to provide more information in the petition than they would be required to provide under proposed § 100.1 and provide interested persons with an opportunity to have an oral hearing on whether a petition should be granted.

The agency does not believe that the medical device regulations on exemption petitions are an appropriate model for implementing the 1990 amendments. The statutory provisions under which the medical device regulations were promulgated are different from the 1990 amendments in a fundamental respect. The medical device statutory provisions require a hearing. The 1990 amendments do not. Consequently, the agency chose to model its regulations after the CPSC regulations rather than the medical device regulations because the CPSC regulations provided a mechanism in which no hearing is required.

Moreover, the agency believes that the information proposed by FDA for submission by a State in its exemption petition is appropriate because it responds directly to the criteria established by section 403A(b) of the act. Accordingly, FDA is not making the suggested changes.

12. Several comments requested that FDA provide for the periodic review of granted exemptions and for the revocation of an exemption if the conditions that were present when the exemption was granted no longer exist. One comment noted that the medical device procedures provide for such revocation of previously granted exemption petitions.

The agency understands the concerns expressed by these comments and is open to citizen petitions to revoke an exemption if such revocation is warranted. However, the agency does not have the resources to commit itself to periodic reviews of exemptions granted to States. If an interested person becomes aware of a change in the conditions that led FDA to grant an exemption, that person can submit a citizen petition under § 10.30 *Citizen petition* (21 CFR 10.30) requesting revocation of that exemption. The agency will review any such petition that is submitted. If the petition shows that the conditions that justified an exemption no longer exist, the agency will consider revoking that exemption.

C. What the Petition Must Show About Effect on Interstate Commerce

13. Several comments suggested that FDA should balance a State or locality's particular need against the burden on interstate commerce in determining whether an exemption petition should be granted.

The agency does not believe that the test for whether a State requirement does, in fact, "unduly burden" interstate commerce is one of balancing burden versus need. The statute anticipates that a State or locality's need for a particular labeling requirement will be assessed separately under section 403A(b)(3). In case law interpreting "undue burden," the court equated the term with unfairness. (See *Mid-South Bottling Co. v. NLRB*, 876 F.2d 458, 461 (5th Cir. 1989)). Applying this unfairness standard, one could argue, for example, that if a State requirement can be readily accommodated (e.g., a stick-on label) or is not applied to out-of-state firms, it does not unduly burden interstate commerce. On the other hand, if the State requirement required a completely different label than would be appropriate everywhere else in the country, a strong argument could be made that it does unduly burden interstate commerce. Accordingly, the agency is not including the suggested balancing test as a criterion for determining whether a State's petition for exemption from preemption should be granted.

14. Several comments objected to the amount of information required in a State petition on the effect that granting it will have on interstate commerce. These comments were particularly

opposed to the agency's position that States should obtain information in the form of statements from producers of food products indicating that it is practical and feasible for them to comply with the State requirement.

The congressional intent in enacting the 1990 amendments was to provide national uniformity and to allow industry to conduct business in an efficient and cost-effective manner (136 Congressional Record H12954, October 26, 1990). Accordingly, the State has the burden to show why an exemption is appropriate, and why such an exemption, if granted, would not unduly burden interstate commerce.

To meet this burden, a State will need to contact industry to determine the effect of its regulations upon interstate commerce. Although a company may say that the burden is significant, the State would have the opportunity to show as part of its petition that the company's view is overstated and, therefore, does not provide a basis for denying the petition. Accordingly, the agency is retaining this requirement in the final rule.

15. Some comments requested that FDA require States to include more information in their petitions to show not only the costs of distributing products labeled differently for different States but also the cost of changing labels if an exemption petition is granted.

The agency proposed in § 100.1(d)(2) (Part C, Statement of Grounds) to only provide States with guidance as to what a petition for exemption from preemption should contain. The agency continues to believe, and it was not persuaded by the comments to conclude otherwise, that it is not appropriate to establish requirements on the contents of a State petition for an exemption from preemption. Therefore, FDA rejects the comments on this point. However, the agency does agree that the costs of changing labels and of using different labels in different localities bear on the issue of burden on interstate commerce and, therefore, should be included in the State's petition as part of the cost of compliance.

16. Some comments suggested that, with respect to possible burdens on interstate commerce, FDA should give more specific guidance about what it intends to consider in deciding whether to grant an exemption from preemption for a State or local requirement. One comment stated that the factors depicted in proposed § 100.1(d)(2) (i.e., economic feasibility, comparison of costs of compliance, effects on the availability of a food to consumers, and the practicality of industry compliance) do not accurately or fully summarize the constitutional considerations employed by Federal courts. The latter comment suggested that a State must be able to show: (1) The important public interests its regulation supposedly furthers, (2) that the regulation treats in-state and out-of-state manufacturers or advertisers evenhandedly, (3) the degree of burden imposed by the regulation, (4) that the burden is not clearly excessive in relation to any putative local benefits, (5) that the regulation does not project the State's standards into other States, and (6) that the regulation does not unduly impede the free flow of interstate commerce.

The agency believes that the guidance that it has provided in § 100.1(d)(2) (Part C, Statement of Grounds) as to the information necessary to support an exemption petition fully reflects the considerations that the Federal courts have applied in determining whether there is an undue burden on interstate commerce. The agency, however, with the exception of item (2) above, does not object to a State addressing the listed items in an exemption petition. With respect to item (2), the agency notes that it does not have jurisdiction over products manufactured and distributed in intrastate commerce, nor does it have jurisdiction over advertising, which is regulated by the Federal Trade Commission. Therefore, FDA considers this item to be of marginal relevance to the determination that the agency must make.

D. Particular Need for Information

17. Several comments argued that FDA has misinterpreted the portion of the 1990 amendments requiring a State to show a "particular need for information" to mean that a State or locality must show that a labeling requirement fulfills a unique local need in order to exempt a requirement from preemption. The comments stated that a petition for exemption from preemption should not be denied simply because the need for information is also national in scope.

While the agency agrees with the comments' interpretation of the statute, an agency decision to grant an exemption from preemption is likely to be based largely on the agency's evaluation of the situation within the requesting State. If the need for an exemption is not only local, the agency is likely to consider whether it would not in fact be more appropriate to amend the relevant Federal regulation rather than grant an exemption. Therefore, while the agency is open and willing to consider any need for exemption asserted in a State petition, it seems prudent for such a petition to address the question of why the agency should limit its consideration to the exemption and not address the broader concern.

18. One comment suggested that FDA include a provision in the final rule that requires that petitions for exemption that are based on a claim that a particular Federal requirement fails to meet the petitioning State's particular local need be accompanied by a citizen's petition under § 10.30 to amend the Federal requirement. The comment said that the agency should defer consideration of the exemption petition until it has ruled on the citizen's petition.

The agency does not believe that such a requirement is appropriate or necessary. It would be an unnecessary burden on States to require that they submit all the information necessary for a citizen petition to amend FDA's regulations. The agency, however, has no objection to other interested persons submitting a citizen petition under § 10.30 for an amendment to a Federal regulation. Although the agency cannot commit itself to acting on such citizen petition first, it will review it as appropriate and in an expeditious manner.

19. Several comments suggested that States should be required to identify alternatives that might be used to meet the need for information without negating Federal preemption and to explain why those alternatives could not be reasonably implemented within the State. These comments argued that this requirement would satisfy the State's burden to prove that uniformity should be compromised. Not every perceived shortcoming in Federal requirements, the comment stated, must be remedied by different labeling requirements.

The 1990 amendments provide only that a State show that its requirement would not cause any food to be in violation of Federal law, would not unduly burden interstate commerce, and is designed to meet a particular need for information that is not met by the Federal requirements. There is no provision in the 1990 amendments that requires that the States identify and consider a number of alternatives beyond that for which it is seeking exemption from preemption. Accordingly, FDA is not including the suggested provision in the final rule.

V. Procedural Provisions

A. When to File—Submission of Petition Before a State Rule is Finalized

20. Several comments disagreed with the proposed requirement in § 100.1(c)(1) that States submit an exemption petition only after the State requirement has been enacted or issued as a final rule by an authorized State official and is in effect or would be in effect but for the provisions of section 403A of the act. The comments suggested that States be allowed to petition for exemption at any time once a State rulemaking proceeding starts, or when the State believes that the rule will become final. The comments said that it would be too burdensome to promulgate a State regulation only to have it preempted by the Federal regulation. The comments also requested guidance from FDA about preemption and its effects on current and possible future State laws.

Acceptance of a State petition for exemption from preemption for a State law or regulation that has not been enacted or promulgated could result in a waste of FDA resources if the State subsequently decides not to enact the law or not to adopt the regulation. FDA is willing to communicate and work with States when questions about preemption arise. However, the agency does not believe that it is prudent to accept exemption petitions for laws or regulations that are not yet enacted. Because preemption can only occur if there is a State law or regulation in effect, the agency will not grant an exemption to a proposed State law or regulation.

The agency, however, advises that a State should be aware of the possible preemption problems at the time it considers whether to adopt the law or regulation. Realizing that the primary purpose of preemption is uniformity of State laws, the State will need to find that there are particular needs that compel it to adopt the law or regulation if it is to do so in the face of the likelihood of preemption. Those are exactly the needs that ought to be brought to the agency's attention as part of the exemption from preemption process.

B. Filing State Exemption Petitions

21. Several comments recommended that proposed § 100.1(c) be revised in the final rule to set "threshold requirements for the acceptance of petitions for suitability for filing of State petitions." The comments noted that the proposed prerequisites would establish only that there is a State requirement, that the State and Federal requirements are not identical, and that the petitioner is an appropriate State official. These comments suggested that FDA not accept for filing in the first instance any exemption petition unless it contains a prima facie showing that the statutory prerequisites are met; i.e., that the proposed exemption will not result in a violation of any Federal law, will not unduly burden interstate commerce, and is designed to address a particular need for information that is not met by the preemptive Federal requirement (section 403A(b) of the act). One comment viewed a demonstration of threshold compliance with the statutory prerequisites as critical in light of the fact that under section 10(b)(2) of the 1990 amendments, a petition submitted by May 8, 1992, has the effect of staying Federal preemption until FDA takes action on the petition. The comment was concerned that because the State petitioning regulation itself is not proposed to become effective until November 8, 1992, FDA action on State petitions submitted before May 8, 1992, will be deferred for a very long time. Consequently, the comment argued that without a meaningful petition threshold regulation, even a State petition unapprovable on its face would stay Federal preemption for that time.

The agency believes that the threshold requirements it proposed in § 100.1(c) are more than adequate for determining whether a petition for exemption from preemption should be accepted for filing. The requested prima facie showing that the exemption petition has met the statutory prerequisites goes to the merits of the petition, and whether it should be granted or denied, not to whether it is suitable for filing. Given this fact, along with the complexities of the factors to be considered in determining whether the statutory prerequisites have been met by the petitioner, and the amount of time (90 days) in which the agency is expected to make a final decision on the merits of each exemption petition, FDA is not amending § 100.1(c) to grant the comments' request.

The agency notes that the suggested inclusion of additional threshold requirements for the acceptance of exemption petitions will not address the concerns expressed by the comments. The comments address the provision of section 10(b)(2) of the 1990 amendments that exempts a State requirement described in section 403A(a)(3) through (a)(5) of the act from preemption for a limited period of time if the State submits a petition under section 403A(b) of the act by May 8, 1992. Because the time limit of May 8, 1992, for submitting exemption petitions that would temporarily except State requirements from preemption has passed, any value in establishing threshold requirements for petitions submitted by that date is moot. Moreover, the agency does not believe that it can retroactively establish threshold requirements that would exclude certain or all State petitions from the exemption provisions of section 10(b)(2) of the 1990 amendments.

22. Several comments recommended that § 100.1(f)(4) and (f)(5) be revised to provide for public notification in the **Federal Register** of the filing of State exemption petitions. One comment suggested that a notice of filing of an exemption petition be sent to the petitioner. Some comments also recommended that FDA provide for a comment period between the filing of an exemption petition and the agency's response. Other comments wanted the submission of an exemption petition and the agency's responses to be made public. These comments expressed concern that without public notification, an interested person may not know that his or her interests require the filing of comments. Some comments suggested that FDA also should establish a specific time between the receipt and the filing of an exemption petition so that interested persons may provide meaningful comment.

The agency does not believe public notification in the **Federal Register** of the submission or filing of exemption petitions is necessary. Nor does the agency find it necessary to establish a comment period for either submitted or filed petitions. The procedures for the handling of petitions for exemption from preemption are generally consistent with those in § 10.30 for citizen petitions. Section 100.1(e) provides that once an exemption petition is accepted for filing, it will be made available for public examination and copying at the Dockets Management Branch under the rules provided for in § 10.20(j) (21 CFR 10.20(j)). In addition, § 100.1(f)(3) provides that the petitioner will be notified in writing of the filing and docket number of the petition. Section 100.1(f)(4) allows any interested person to submit written comments to the Dockets Management Branch on a filed petition, as provided in § 10.30(d). If the agency tentatively decides that an exemption petition has merit, it will publish in the **Federal Register** a proposal to grant the exemption, and interested persons will have an opportunity to comment on the proposal at that time.

The agency recognizes that not providing for a public notice of the filing or submission of an exemption petition in the procedures that it is establishing may limit the ability of a person who might consider the petition significant to comment on the petition before the agency makes a decision to propose to grant the exemption or to deny the petition. The agency has concluded, however, that there is no prejudice from this fact because the petition will be available at the Dockets Management Branch, comments can be submitted on the petition, and the agency will not grant the petition until after there has been rulemaking on whether such action is appropriate. Interested persons will thus have ample opportunity to comment on the petition.

23. One comment requested that FDA establish a comment period for accepting comments to a proposal to grant an exemption.

The agency points out that all FDA published proposals are subject to the requirements of § 10.40 *Promulgation of regulations for efficient enforcement of the law* (21 CFR 10.40). Section 10.40(b)(2) provides that the proposal will provide 60 days for comment, although the Commissioner of Food and Drugs may shorten the comment period (to not less than 10 days) or lengthen this time period for good cause.

24. One comment said that FDA should make a decision on the exemption petition in 90 days and not just issue a response that it has not made a decision.

The agency advises that it intends to make every effort to make its decisions on exemption petitions within the 90-day period. However, there are circumstances that arise, such as other agency priorities and a need for additional information, that may not permit the agency to respond within 90 days. Accordingly, the agency has concluded that a provision for a tentative response, similar to that which is permitted in § 10.30(e)(2)(iii), is both appropriate and warranted.

25. Some comments wanted FDA to publish a list of all petitions filed before May 8, 1992, and to act promptly on these petitions.

Five petitions from States requesting exemption from preemption were submitted to the agency by May 8, 1992. As announced in the **Federal Register** of March 14, 1991 (56 FR 10906), the agency has deferred action on these petitions and has not reviewed them to any extent at this time. These petitions are: State of California petitions on milk, dated January 7, 1991 (Docket No. 91P–0009); slack fill, dated May 6, 1992 (Docket No. 92P–0361); bottled water, dated May 8, 1992 (Docket No. 92P–0216); State of Michigan petition on nonalcoholic beverages, dated March 15, 1991 (Docket No. 92P–0360); State of Vermont petition on maple syrup, dated July 30, 1991 (Docket No. 92P–0359); and a joint petition by 44 states, territories or jurisdictions on net content, dated November 9, 1992 (Docket No. 92P–0441). The agency fully intends to respond to these petitions in the very near future.

26. One comment from a foreign country requested that FDA notify it of any State exemption petitions that could affect trade. The comment expressed concern that any exemptions not violate the General Agreement on Tariffs and Trade or the Free Trade Agreement with Canada.

The agency advises that if it should tentatively decide that an exemption petition has merit, it will publish a proposal in the **Federal Register** to grant the exemption through rulemaking. Any foreign government concerned about trade implications would have an opportunity to comment on such a proposal at that time. The agency believes that publication of proposals to grant an exemption in the **Federal Register** will provide adequate notice to foreign governments of State petitions for exemption from preemption.

C. Exemption Granted through Notice and Comment Rulemaking

27. Several comments were opposed to granting exemptions through rulemaking. The comments said there is nothing in the language of the 1990 amendments indicating the necessity for issuing exemptions in the form of regulations.

The agency considered these comments but finds no basis to change its tentative conclusion that granting of exemptions through notice and comment rulemaking is the best procedure to follow. The agency believes that rulemaking is appropriate because section 403A(b) provides that FDA is to grant the exemption by regulation, and because the granting of an exemption from preemption will have the force and effect of law. In addition, rulemaking will ensure that all interested persons have an opportunity to comment, and that all opinions are expressed. Accordingly, FDA is retaining § 100.1(f)(5)(i), as proposed, but is adding the phrase "under such conditions as it [FDA] may prescribe by regulation" to the last sentence of § 100.1(a)(2) to reflect the language of section 403A(b).

After considering the comments that FDA received on the proposal, FDA is adding a new subpart A, consisting of § 100.1.

VI. Paperwork Reduction Act

Section 100.1(d) of this final rule contains information collection requirements that were submitted for review and approval to the Director of the Office of Management and Budget (OMB), as required by section 3504(h) of the Paperwork Reduction Act of 1980. The requirements were approved and assigned OMB control number 0910–0277.

VII. Economic Impact

In its November 1991 proposal, FDA concluded that the proposed requirements did not constitute a major rule and that no significant impact on a substantial number of small entities, including small businesses, would derive from this action. FDA has not received any new information or comments on the proposal that would alter its previous determination.

VIII. Environmental Impact

The agency previously determined under 21 CFR 25.24(a)(8), as announced in the proposed rule and published in the **Federal Register** of November 27, 1991 (56 FR 60528), that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. No new information or comments have been received that would affect the agency's previous determination that there is no significant impact on the human environment and that an environmental assessment or an environmental impact statement is not required.

List of Subjects in 21 CFR Part 100

Administrative practice and procedure, Food labeling, Foods.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 100 is amended as follows:

PART 100—GENERAL

1. The authority citation for 21 CFR part 100 is revised to read as follows:

Authority: Secs. 201, 301, 307, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 337, 342, 343, 348, 371).

2. A new subpart A consisting of § 100.1 is added to read as follows:

Subpart A—State and Local Requirements

§ 100.1 Petitions requesting exemption from preemption for State or local requirements.

(a) *Scope and purpose.* (1) This subpart applies to the submission and consideration of petitions under section 403A(b) of the Federal Food, Drug, and Cosmetic Act (the act), by a State or a political subdivision of a State, requesting exemption of a State requirement from preemption under section 403A(a) of the act.

(2) Section 403A(b) of the act provides that where a State requirement has been preempted under section 403A(a) of the act, the State may petition the agency for an exemption. The agency may grant the exemption, under such conditions as it may prescribe by regulation, if the agency finds that the State requirement will not cause any food to be in violation of any applicable requirement under Federal law, will not unduly burden interstate commerce, and is designed to address a particular need for information that is not met by the preemptive Federal requirement.

(b) *Definitions.* (1) *Act* means the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321 *et seq.*).

(2) *Agency* means the Food and Drug Administration.

(3) *Commissioner* means the Commissioner of Food and Drugs.

(4) *State* means a State as defined in section 201(a)(1) of the act (which includes a territory of the United States, the District of Columbia, and Puerto Rico) or any political subdivision of a State having authority to issue food standards and food labeling regulations having force of law.

(5) *State requirement* means any statute, standard, regulation, or other requirement that is issued by a State.

(c) *Prerequisites for petitions for exemption from preemption.* The Food and Drug Administration will consider a petition for exemption from preemption on its merits only if the petition demonstrates that:

(1) The State requirement was enacted or was issued as a final rule by an authorized official of the State and is in effect or would be in effect but for the provisions of section 403A of the act.

(2) The State requirement is subject to preemption under section 403A(a) of the act because of a statutory provision listed in that section or because of a Federal standard or other Federal regulation that is in effect, or that has been published as a final rule with a designated effective date, and that was issued under the authority of a statutory provision listed in that section. For the purposes of this subpart, all petitions seeking exemption from preemption under section 403A(a)(3) through (a)(5) of the act submitted before May 8, 1992, will be considered timely even though the applicable statutory provisions or regulations are not yet in effect.

(3) The petitioner is an official of a State having authority to act for, or on behalf of, the Government in applying for an exemption of State requirements from preemption.

(4) The State requirement is subject to preemption under section 403A(a) of the act because it is not identical to the requirement of the preemptive Federal statutory provision or regulation including a standard of identity, quality, and fill. "Not identical to" does not refer to the specific words in the requirement but instead means that the State requirement directly or indirectly imposes obligations or contains provisions concerning the composition or labeling of food, or concerning a food container, that:

(i) Are not imposed by or contained in the applicable provision (including any implementing regulation) of section 401 or 403 of the act; or

(ii) Differ from those specifically imposed by or contained in the applicable provision (including any implementing regulation) of section 401 or 403 of the act.

(d) *Form of petition.* (1) All information included in the petition should meet the general requirements of § 10.20(c) of this chapter.

(2) An original and one copy of the petition shall be submitted, or the petitioner may submit an original and a computer readable disk containing the petition. Contents of the disk should be in a standard format, such as ASCII format. (Petitioners interested in submitting a disk should contact the Center for Food Safety and Applied Nutrition for details.)

(3) Petitions for exemption from preemption for a State requirement shall be submitted to the Dockets Management Branch in the following form:

(Date) ————————

Dockets Management Branch,
Food and Drug Administration,
Department of Health and Human Services,
rm. 1–23, 12420 Parklawn Dr.,
Rockville, MD 20857.

Petition Requesting Exemption from Preemption for State Requirement

The undersigned submits this petition under section 403A(b)of the Federal Food, Drug, and Cosmetic Act to request that the Food and Drug Administration exempt a State requirement from preemption.

The undersigned has authority to act for, or on behalf of, the (*identify State or political subdivision of the State*) because (*document petitioner's authority to submit petition on behalf of the State*).

A. Action Requested

1. Identify and give the exact wording of the State requirement and give date it was enacted or issued in final form.

2. Identify the specific standard or regulation that is believed to preempt the State requirement and the section and paragraph of the act that the standard or regulation implements.

B. Documentation of State Requirement

Provide a copy of the State requirement that is the subject of the application. Where available, the application should also include copies of any legislative history or background materials used in issuing the requirement, including hearing reports or studies concerning the development or consideration of the requirement.

C. Statement of Grounds

A petition for an exemption from preemption should contain the following:

1. An explanation of the State requirement and its rationale, and a comparison of State and Federal requirements to show differences.

2. An explanation of why compliance with the State requirement would not cause a food to be in violation of any applicable requirement under Federal law.

3. Information on the effect that granting the State petition will have on interstate commerce. The petition should contain information on economic feasibility, i.e., whether the State and Federal requirements have significantly different effects on the production and distribution of the food product; comparison of the costs of compliance as shown by data or information on the actual or anticipated effect of the State and Federal requirements on the sale and price of the food product in interstate commerce; and the effect of the State requirement on the availability of the food product to consumers. To the extent possible, the petition should include information showing that it is practical and feasible for producers of food products to comply with the State requirement. Such information may be submitted in the form of statements from affected persons indicating their ability to comply.

4. Identification of a particular need for information that the State requirement is designed to meet, which need is not met by Federal law. The petition should describe the conditions that require the State to petition for an exemption, the information need that the State requirement fulfills, the inadequacy of the Federal requirement in addressing this need, and the geographical area or political subdivision in which such need exists.

D. Environmental Impact

The petition shall contain a claim for categorical exclusion under 21 CFR 25.24 or an environmental assessment under 21 CFR 25.31.

E. Notification

Provide name and address of person, branch, department, or other instrumentality of the State government that should be notified of the Commissioner's action concerning the petition.

F. Certification

The undersigned certifies, that, to the best knowledge and belief of the undersigned, this petition includes all information and views on which the petition relies.

(Signature) _____

(Name of petitioner) _____

(Mailing address) _____

(Telephone number) _____

(Information collection requirements in this section were approved by the Office of Management and Budget (OMB) and assigned OMB number 0910–0277)

(e) *Submission of petition for exemption; public disclosure.* The availability for public disclosure of a petition for exemption will be governed by the rules specified in § 10.20(j) of this chapter.

(f) *Agency consideration of petitions.* (1) Unless otherwise specified in this section, all relevant provisions and requirements of subpart B of part 10 of this chapter, are applicable to State petitions requesting exemption from Federal preemption under section 403A(b) of the act.

(2) If a petition does not meet the prerequisite requirements of paragraph (c) of this section, the agency will issue a letter to the petitioner denying the petition and stating in what respect the petition does not meet these requirements.

(3) If a petition appears to meet the prerequisite requirements in paragraph (c) of this section, it will be filed by the Dockets Management Branch, stamped with the date of filing, and assigned a docket number. The docket number identifies the file established by the Dockets Management Branch for all submissions relating to the petition, as provided in this part. Subsequent submissions relating to the matter must refer to the docket number and will be filed in the docket file. The Dockets Management Branch will promptly notify the petitioner in writing of the filing and docket number of a petition.

(4) Any interested person may submit written comments to the Dockets Management Branch on a filed petition as provided in § 10.30(d) of this chapter.

(5) Within 90 days of the date of filing the agency will furnish a response to the petitioner. The response will either:

(i) State that the agency has tentatively determined that the petition merits the granting of an exemption, and that it intends to publish in the **Federal Register** a proposal to grant the exemption through rulemaking;

(ii) Deny the petition and state the reasons for such denial; or

(iii) Provide a tentative response indicating why the agency has been unable to reach a decision on the petition, e.g., because of other agency priorities or a need for additional information.

(g) If a State submitted a petition for exemption of a State requirement from preemption under section 403A(a)(3) through (a)(5) of the act before May 8, 1992, that State requirement will not be subject to preemption until:

(1) November 8, 1992; or

(2) Action on the petition, whichever occurs later.

Dated: October 26, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Food and Drug Administration

21 CFR Ch. I

[Docket No. 91N–0134]

Certain Misbranding Sections of the Federal Food, Drug, and Cosmetic Act That Are, and That Are Not, Adequately Being Implemented by Regulation; Notice of Final Lists

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is publishing, in accordance with the Nutrition Labeling and Education Act of 1990 (the 1990 amendments), final lists delineating which of six sections of the Federal Food, Drug, and Cosmetic Act (the act) that define circumstances in which a food is misbranded are adequately being implemented by FDA regulations and which are not. These six sections are: Sections 403(b) (offered for sale under the name of another food), 403(d) (misleading container), 403(f) (information of appropriate prominence), 403(h) (compliance with standard of quality and fill), 403(i)(1) (common or usual name), and 403(k) of the act (declaration that the product contains artificial flavoring, coloring, or preservatives) (21 U.S.C. 343(b), 343(d), 343(f), 343(h), 343(i)(1), and 343(k)).

Based upon its evaluation of the recommendations of the National Academy of Sciences, Institute of Medicine, Food and Nutrition Board (hereinafter referred to as IOM), its consideration of the comments on the proposed lists, and other available information, the agency finds that all but section 403(d) of the act are adequately being implemented.

EFFECTIVE DATE: The final lists of sections of the act that are, and that are not, being adequately implemented become effective on February 5, 1993.

FOR FURTHER INFORMATION CONTACT: Gerad L. McCowin, Center for Food Safety and Applied Nutrition (HFS–151), Food and Drug Administration, 200 C. St. SW., Washington, DC 20204, 202–205–5162.

SUPPLEMENTARY INFORMATION:

I. Background

In response to section 6(b) of the 1990 amendments (Pub. L. 101–535), FDA published in the **Federal Register** of July 28, 1992 (57 FR 33283), proposed lists that identified which of six sections of the act (sections 403(b), 403(d), 403(f), 403(h), 403(i)(1), and 403(k)) that define circumstances in which a food is misbranded are adequately being implemented by FDA regulations and which are not adequately being implemented. The agency tentatively concluded that sections 403(b), 403(f), 403(h), 403(i)(1), and 403(k) of the act are adequately being implemented, and that section 403(d) is not adequately being implemented. FDA's tentative conclusions were based on the recommendations of IOM, with whom FDA had contracted, in accordance with section 6(b) of the 1990 amendments, to study:

(A) State and local laws that require the labeling of food that is of the type required by sections 403(b), 403(d), 403(f), 403(h), 403(i)(1), and 403(k) of the Federal Food, Drug, and Cosmetic Act, and

(B) the sections of the Federal Food, Drug, and Cosmetic Act referred to in subparagraph (A) and the regulations issued by the Secretary to enforce such sections to determine whether such sections and regulations adequately implement the purposes of such sections.

Interested persons were given until September 28, 1992, to comment. FDA received six letters, each containing one or more comments, from two trade organizations, a food manufacturer, a professional organization, and a consumer organization. A summary of the issues raised by the comments and the agency's responses follow.

II. Response to Comments

A. Adequate Implementation

1. One comment objected to the criteria used by IOM to determine whether a particular section is adequately being implemented. Specifically, the comment interpreted the legislative history to provide that "adequate implementation" means full implementation of the six misbranding sections and thus requires Federal adoption of the strongest legal standards that effectively accomplish the goals of the provisions under study. The comment stated that:

> IOM's conclusions are contrary to the NLEA because the legislative history indicates that Congress intended to avoid preempting state and local governments unless the FDCA has been fully implemented, and no additional federal regulation is necessary.

The agency disagrees with this comment. The agency can find no support in the legislative history or in the 1990 amendments for a conclusion that the intent of the procedures established by section 6(b) was to identify the strongest regulations relevant to each of the six sections listed in section 403A(a)(3) of the act and to have FDA adopt those regulations.

In discussing the preemption provisions of the 1990 amendments, Congressman Waxman identified two principles that should be considered in preempting State laws. First, State laws should not be preempted unless the nature of the laws at issue makes it difficult and even impossible for companies to operate in interstate commerce. Secondly, the States should never be preempted unless a strong Federal regulatory system is in place (136 Congressional Record H5840 (July 30, 1990)). Mr. Waxman noted that the requirements for nutrition labeling and for health claims that were in the bill that had been reported out of the House Committee on Energy and Commerce (and that became the 1990 amendments) created such a strong regulatory system (id.). Implicitly, Congress also recognized the strength and adequacy of FDA's implementation of sections 401 of the act (standards of identity) and 403(g) of the act (standards of identity labeling) to which it gave preemptive effect on the date of enactment and of sections 403(c) (imitation foods), 403(e) (name and address of responsible firm and net contents declaration), and 403(i)(2) of the act (ingredient labeling) which Congress made preemptive 1 year after enactment.

However, Mr. Waxman stated that Congress was unable to determine whether the Federal standard is strong in the areas covered by sections 403(b), 403(d), 403(f), 403(h), 403(i)(1), and 403(k) of the act (136 Congressional Record H5840). Thus, he said, the bill provides for a study of Federal and State standards to determine whether additional Federal regulations on each of the sections is needed.

Further information on the nature of the study is provided by the House Manager's report:

> The purpose of this study is to provide the Secretary information upon which to determine whether federal laws are adequate once the state laws are preempted. It is anticipated that the study will identify all federal regulations that are applicable as well as State laws that will be preempted. The study should also survey local laws, but it is not anticipated that every local law will need to be identified.

(136 Congressional Record H5842 (July 30, 1990)).

It is clear from this legislative history that what Congress intended was for FDA, through a contractor, to compare its regulations implementing the sections of the act in question with those of the States. To the extent that

that study identified major matters covered by those sections that the States were addressing but FDA was not, FDA would have to address those matters before the sections in question would be preemptive.

However, there is nothing in the statute or the legislative history that suggests that the purpose of the study was to identify the strongest State standard on each of the matters covered by those sections of the act and for FDA to implement that provision. Therefore, FDA rejects this comment.

2. One comment stated that the IOM had erred in failing to consider the level of FDA enforcement in determining whether a particular section has been adequately implemented.

The agency disagrees that its enforcement record is appropriately a factor in determining adequacy of implementation. There is nothing in the act or the legislative history that would indicate that it should be. Nor does it make any sense in light of the legislative history that level of enforcement is a relevant factor. Congress cited nutrition labeling and health claims as topics on which a strong Federal regulatory system is in place, even though the statutory provisions on these topics had never been enforced (136 Congressional Record H5840 (July 30, 1990)). Apparently, Congress did so because it anticipated that adoption of the regulations necessary in response to the 1990 amendments would establish such a strong regulatory system. Thus, it is appropriate to look to the regulatory systems in place for each of the sections in question—that is, to the regulations that effect those sections—to determine whether they are adequately being implemented.

3. One comment stated that IOM cannot legally determine whether a particular section is adequately being implemented without considering the level of industry compliance.

FDA disagrees. Because IOM received no information from FDA or the States concerning industry compliance, and because only anecdotal information exists, IOM concluded that there was no objectively verifiable data regarding compliance that could be used to evaluate adequacy of implementation of the misbranding sections. Therefore, IOM decided that to evaluate compliance on the basis of such limited data would be contrary to the intent of the 1990 amendments.

Again, there is nothing in the legislative history that would suggest that industry compliance was a factor that either IOM or FDA should consider in deciding whether the Federal regulations implementing the sections in question are adequate. If compliance is a problem, what the statute seems to contemplate is that FDA would establish a strong national standard that the States and the agency would then work together to enforce. As Congressman Waxman said: "Third, any preemption provision must recognize the important contribution that the State can make in regulation, and it must leave a role for the states." (136 Congressional Record H5840 (July 30, 1990)). Thus, FDA rejects this comment.

B. Preemption

4. One comment argued that IOM misinterpreted the 1990 amendments as to the extent of preemption by concluding that all State and local requirements, not just those that conflict with Federal law, should be preempted if FDA determines that the section under study has, as a whole, adequately been implemented. The comment argued that the national uniformity portion of the 1990 amendments was intended to ease the burden to industry by preempting inconsistent labeling requirements. The comment stated that, therefore, State and local requirements that serve consumer protection purposes should only be preempted if they conflict with FDA regulations.

The comment noted as an example that under IOM interpretation, a State requirement for a common or usual name for a particular product would be preempted even if there is no Federal requirement for a common or usual name for that product. The comment summarized its position by concluding that the IOM had incorrectly interpreted which State and local requirements were "of the type" or "related to" the six areas under study. As support for its position, the comment cited the FDA November 27, 1991, proposal entitled "State Petitions Requesting Exemption From Federal Preemption" (hereinafter referred to as the State petitions proposal) (56 FR 60528).

The agency disagrees with this comment. The comment misinterprets the extent of preemption that occurs under section 403A of the act.

FDA sought to address this issue in its proposal on State petitions for exemption from preemption. In that proposal the agency stated:

> Section 403A is only operative in matters where there is a Federal requirement applicable to the labeling addressed in the State requirement. If there is no applicable Federal requirement that has been given preemptive status by Congress, there is no competing claim of jurisdiction, and, therefore, no basis under the 1990 amendments for Federal preemption or grounds to justify the submission of a State petition for exemption.

(56 FR 60528 at 60530)

In discussing examples of State laws that would not be preempted, FDA listed the following:

> The examples included State laws pertaining to issues for which there is no national framework, such as open date labeling, unit price labeling, container deposit labeling, religious dietary labeling, and previously frozen labeling.

These examples do not include situations that are covered by the sections of the act that are given preemptive effect by section 6(b) of the 1990 amendments or regulations issued under those sections. With respect to those sections, however, the preemptive effect is quite broad. Section 403A(a)(3) of the act, for example, states that no State or political subdivision of a State may directly or indirectly establish or continue in effect as to any food in interstate commerce "* * * any requirement of the type required by section 403(b), 403(d), 403(f), 403(h), 403(403(i)(1), or 403(k) that is not identical to the requirement of such section." Thus, under this provision, as is discussed below in this document and as explained more fully in the final rule entitled "State Petitions Requesting Exemption from Federal Preemption," published elsewhere in this issue of the **Federal Register**, a State common or usual name regulation promulgated in conformance with the requirements of § 102.5 (21 CFR 102.5) for a food for which there is no specific Federal common or usual name would apparently be preempted. It would be a requirement of the type required by section 403(i)(1) of the act, but it would not be identical to the provisions that FDA has adopted under that section.

C. The Six Misbranding Sections Under Review

1. Section 403(b)—Offered for Sale Under the Name of Another Food

5. Four comments supported FDA's tentative determination that section 403(b) of the act is adequately being implemented. However, one comment argued that section 403(b) of the act is not adequately being implemented because FDA has issued no regulations under this section nor has it prosecuted many cases under this section. The comment also noted that IOM, while finding section 403(b) of the act adequately implemented, suggested that FDA should promote the development and introduction of new foods by pursuing more aggressively the regulatory options that will allow the formal naming of new nonstandardized foods.

Having considered the comments to the proposal, the IOM report, and other available information, the agency concludes that IOM was correct in its recommendation, and is finding that section 403(b) of the act is adequately being implemented. The agency notes, as did IOM, that it does have a regulation that implements section 403(b) of the act, § 101.18 *Misbranding of food* (21 CFR 101.18). Moreover, none of the comments pointed to State regulations that implement provisions that are similar to section 403(b) of the act that address matters not covered by FDA's regulations.

As to the enforcement, or lack thereof, of section 403(b) of the act, FDA agrees that there are not many actions brought against manufacturers solely under this general misbranding provision. Any such action taken by FDA against a manufacturer under section 403(b) of the act would almost always be brought in conjunction with counts that charge a violation of the more specific misbranding provisions of section 403, namely section 403(g) (standards of identity) and section 403(i)(1) (common or usual name). However, as discussed above, the level of enforcement is not relevant to the inquiry mandated by Congress.

The agency believes that IOM's suggestion that FDA actively pursue its regulatory options to allow the formal naming of nonstandardized foods was misinterpreted by the comment. IOM was simply offering a suggestion. There is no indication in IOM's report that IOM believed that there was a problem with the implementation of section 403(b) of the act, as evidenced by its recommended finding that this section is being adequately implemented. For these reasons, FDA rejects this comment.

2. Section 403(d)—Misleading Container

6. Two comments cited FDA's current requirements for net weight declaration and standards of fill regulations as evidence that section 403(d) of the act is adequately being implemented. One of the comments added that IOM's determination that section 403(h) of the act (fill of container) is adequateiy being implemented precluded the IOM from finding that section 403(d) is not adequately being implemented.

The agency disagrees with the comments. The suggestion that the provisions for net weight declaration (as provided by section 403(e) of the act) and standards of fill (as provided by section 403(h)(2) of the act) serve to implement section 403(d) of the act would basically serve to render section 403(d) of the act a nullity. Although there is clearly an interrelationship among the three sections, the agency believes that the presence of an accurate net weight statement or compliance with a standard of fill does not eliminate the misbranding that occurs when a container is made, formed, or filled so as to be misleading.

7. One comment argued that it would not be cost effective for FDA to implement section 403(d) of the act by promulgating detailed specific commodity and container regulations, such as those the agency has adopted in the past under section 401 of the act and enforced under section 403(h)(2) for all food products or specific food product classes. The comment also argued that further regulatory activity would be inappropriate in light of the IOM's failure to identify any State commodity and package regulations that should be adopted and of FDA's previous determination that the expenditures of agency resources that would be needed to implement such regulations would exceed potential benefits.

FDA disagrees. The fact that IOM was unable to identify any specific state law that FDA should adopt was not a basis for ending their consideration of whether a particular section is being adequately implemented. As noted above, the task was to determine the adequacy of Federal implementation by considering: (1) The extent of State regulation for each topic and the corresponding Federal regulation and (2) whether the States were doing anything that FDA should be doing. FDA notes that IOM did mention California's experience in this area suggested using the provisions of the Fair Packaging and Labeling Act (FPLA) as a guide for Federal regulations to implement section 403(d) of the act.

The agency's earlier decisions not to implement general or individual regulations concerning slack-fill or deceptive packaging were in relation to the efficient utilization of the agency's resources, not the adequate implementation of the intent of section 403(d) of the act. The provisions of the 1990 amendments require that the agency examine its implementation of section 403(d) of the act from a different perspective, i.e., not in terms of efficient use of resources but instead whether its regulations adequately implement the intent of section 403(d) of the act. Based upon the findings of IOM and its own review of the record, FDA concludes that section 403(d) of the act is not adequately being implemented.

8. One comment, without addressing whether the IOM recommendation concerning 403(d) of the act is correct, urged the agency to take whatever action is necessary to implement section 403(d) of the act adequately. The comment suggested that the agency consider using the definition for slack-fill that appears in section 5 of the FPLA. Another comment opposed the proposed determination that section 403(d) of the act is not being adequately implemented by FDA on the basis that the IOM report, in supporting its determination of inadequacy, does no more than suggest that FDA adopt some general regulations merely parroting the language of section 5(c)(4) of the FPLA which: (1) Authorizes FDA to adopt product-by-product regulations to prevent the nonfunctional slack-fill of packages when it finds such regulations are necessary to prevent the deception of consumers or to facilitate value comparisons, and (2) provides that a package shall be deemed to include nonfunctional slack-fill if it is filled to substantially less than capacity for reasons other than: (a) Protection of the contents of such package or (b) the requirements of machines used for enclosing the contents in such package. The comment argued that the adoption of a general regulation to implement statutory language of the FPLA would provide no further guidance to the agency, the public, or the industry than is now provided in the relevant case law under section 403(d) of the act and in the legal literature discussing nonfunctional slack-fill. Moreover, the comment argued, any attempt to write more specific requirements in a general slack-fill regulation would certainly founder on the widely different considerations that apply to different foods and different packages—as is graphically illustrated in the differing fill of container standards adopted by FDA.

The issue here is not how to adequately implement section 403(d) of the act, but whether it is being adequately implemented. Based on the evidence cited by IOM, FDA finds that the States have addressed fill of container matters that are not addressed by FDA's regulations. Therefore, FDA concludes that section 403(d) of the act is not adequately being implemented. Elsewhere in this issue of the **Federal Register**, FDA is publishing a proposal entitled "Misleading Containers; Nonfunctional Slack-fill," which is based on the FPLA definition for nonfunctional slack-fill but goes beyond it in ways that the agency has tentatively found to be appropriate to address the types of concerns that were raised by the latter comment. FDA urges that interested persons comment on that proposal.

3. Section 403(f)—Information of Appropriate Prominence

9. One comment stated that IOM was incorrect in recommending that FDA find that section 403(f) of the act is adequately being implemented. The comment stated that, although numerous regulations have been promulgated under this section, several important problems have not been addressed. For example, the comment cited the IOM report's concern that FDA's current regulations "do not provide as precise a definition of 'conspicuous' and 'prominent' as do some States." The IOM report had expressed concern that this lack of definition may place a greater enforcement burden on FDA. The comment submitted excerpts from "Guidelines for Document Designers," a product of the Document Design Project funded by the National Institute of Education as support for its concern on the readability of labels. The comment noted that there is no Federal regulation against obstructing important label information with, for example, price tags.

The agency disagrees with the comment. While FDA has not adopted as precise a definition for "conspicuous" and "prominent" as some States, the regulations adopted by FDA have specific requirements for placement of mandatory information such as product name, net weight, ingredients, and name and address of manufacturer with specifications for type size. FDA finds that these requirements adequately implement section 403(f) of the act. Although FDA has not explicitly enunciated definitions of "conspicuous" or "prominent", its regulations reflect the standard of prominence and readability in *United States* v. *46 Cases, More or Less, "Welch's Nut Caramels,"* 204 F. Supp. 321, 323 (D.R.I. 1962):

> * * * The Act prescribes no minimum specific standard as to how prominent such statements should be. It would seem that the requirements of said section 403(f) are met in a particular case if such statements are prominent enough to be seen and understood by the ordinary individual who is interested in discovering and learning the information disclosed thereby, and who makes the minimum examination of the package to determine its net weight and the ingredients of the candy contained in said package.

While studies on readability may suggest methods of highlighting label information, the question is whether or not the product meets the legal standard of being seen and understood by the ordinary individual. Section 101.1 requires that the principal display panel "shall be large enough to accommodate all the mandatory label information required * * * with clarity and conspicuousness and without obscuring design, vignettes, or crowding." Section 101.2 requires that all information that must appear either on the principal display panel or the information panel must be prominent and conspicuous, but in no case may the letters or numbers be less than one-sixteenth inch in height unless otherwise exempted. These requirements meet the legal standard by ensuring that the information can be seen and understood by the ordinary individual. Thus, while FDA has not chosen to implement section 403(f) of the act in the same way as some of the States, it has adequately implemented that section and established a strong standard.

As to the issue of obscuring label information, § 101.1 prohibits "obscuring design, vignettes, or crowding." The agency has not adopted more specific regulations regarding obscuring by price tags or other means because these tags are placed on the product at the retail level for the most part, and FDA does not have the resources to police individual food outlets across the nation. While the States do regulate at that level, FDA finds that the language of § 101.1 will give them an appropriate and adequate tool to address this problem.

4. Section 403(h)—Compliance With Standards of Quality and Fill

10. One comment set forth what it considered to be four major problems with IOM's conclusion that section 403(h) of the act is adequately being implemented. First, the comment argued that the statements that a product is substandard provided in § 130.14(a) and (b) (21 CFR 130.14(a) and (b)) do not adequately inform consumers of the reason the product is below standard. The comment suggested that FDA require an additional line in both statements to explain briefly the defect in quality or fill (e.g., similar to that which is provided in § 103.5(b) for bottled water, "contains excessive bacteria"). Secondly, the comment argued that the IOM's conclusion that section 403(h) is adequately being implemented should not be based on the fact that companies rarely use the statement "Below Standards in Quality," because it is equally plausible that companies are simply not complying with the requirement, or that there are insufficient substantive standards of quality, fill, and identity to make this determination. Thirdly, the comment stated that IOM's reliance on the lack of court cases involving section 403(h) of the act is not a valid criterion for determining whether the section is adequately being implemented because it is possible that FDA simply does not enforce this section. Finally, the comment argued that IOM did not consider the adequacy of the substantive standards themselves (i.e., the standards of identity, quality and fill) in determining whether section 403(h) of the act is adequately implemented.

Under section 403(h) of the act, a food is considered misbranded if it purports to be or is represented to be a food for which either a standard of quality or fill of container has been prescribed by regulations under section 401 of the act, and its quality or fill falls below such standards. The purpose of the disclosure requirements in § 130.14 (21 CFR 130.14) is simply to permit manufacturers, if they so choose, to sell a product that is not in compliance with section 403(h) of the act because of inadvertent manufacturing error.

The agency points out that the lack of an additional line in the disclosure statement explaining the defect in quality and fill is not germane to determining whether section 403(h) of the act is adequately being implemented for purposes of section 6(b) of the 1990 amendments. Under section 6(b) of the 1990 amendments, the standard that FDA is to use in determining the adequacy of its implementation of section 403(h) of the act is whether States or localities have adopted laws or regulations to implement requirements of this type that address matters not covered by FDA's regulations. Neither the comment nor the IOM report have shown that there are matters with respect to standards of quality or fill covered by States laws that FDA is not addressing.

With respect to the fact that companies rarely use the disclosure statements (e.g., "Below standard in fill"), the comment offered no evidence, nor is FDA aware of any such evidence, to substantiate that its claim that companies are not complying with section 403(h) of the act is in fact true. FDA's compliance efforts have not produced any evidence to this effect. Therefore, FDA can give no credence to this argument.

The agency notes that the lack of court cases involving section 403(h) of the act is not germane to determining whether this section is adequately being implemented. As noted elsewhere in this document, enforcement is not a criterion for making a determination of adequate implementation.

The last argument put forth by the comment is also not germane because the sufficiency of individual standards is not at issue in determining whether

the agency is adequately implementing section 403(h) of the act.

Therefore, FDA rejects the comment and concludes that section 403(h) of the act is adequately being implemented by its regulations.

5 Section 403(i)(1)—Common or Usual Name

11. One comment stated that the language of the IOM report contradicts IOM's conclusion that section 403(i)(1) of the act is adequately being implemented. The comment stated that the fact that the food industry continues to develop new foods for which no regulated common or usual name exists is evidence that section 403(i)(1) of the act is not adequately being implemented. The comment noted that the areas examined by IOM, i.e., bottled water, honey, fish, oriental noodles, Vidalia onions, and wild rice, are indicative of the fact that State standards offer more consumer protection than Federal standards.

The agency disagrees with the comment. The general regulation for common or usual names (§ 102.5 (21 CFR 102.5)) provides general principles that direct how to name any new food for which an individualized common or usual name regulation or standard of identity does not exist. Section 102.5 provides that:

> The common or usual name of any new nonstandardized food, which may be a coined term, shall accurately identify or describe, in as simple and direct terms as possible the basic nature of the food or its characterizing properties or ingredients. The name shall be uniform among all identical or similar products and may not be confusingly similar to the name of any other food that is not reasonably encompassed within the same name.

In addition, § 102.5 requires that "each class or subclass of food shall be given its own common or usual name that states in clear terms, what it is in a way that distinguishes it from different foods." Section 102.5 also includes percentage labeling requirements for characterizing ingredients in certain foods. It provides that a common or usual name of a food may be established by regulation in 21 CFR part 102, Subpart B (Requirements for Specific Nonstandardized Foods), in 21 CFR part 104 (Nutritional Quality Guidelines for Foods), in a standard of identity regulation (21 CFR part 131 through 169), or in other regulations in Chapter I of Title 21 of the Code of Federal Regulations. It also states that a common or usual name of a food may be established by common usage.

The agency disagrees with the comment's statement that the specific common or usual name examples cited in the comment are indicative that State standards are stronger than Federal standards. The IOM report identifies several foods, including the six mentioned in the comment, for which States had common or usual name requirements but for which there were no Federal requirements. FDA finds, as did IOM, that each of IOM's examples represents a situation that either is not subject to section 403A of the act or calls for a state petition for exemption from preemption under section 403A(b), and that these examples do not demonstrate that the requirements of FDA's regulations do not adequately implement section 403(i)(1) of the act.

The agency notes that of the products cited by the comment, only three would be candidates for a common or usual name regulation. Wild rice, Vidalia onions, and fish. With respect to wild rice, IOM did state in its report that there was a potential for consumer fraud through substitution and blending of the more expensive wild rice with other cheaper rice products. However, the agency has no data, nor was any submitted, to confirm that this in fact is the situation in the marketplace. Moreover, the agency does not believe establishing a specific common or usual name regulation for wild rice would necessarily give the consumer any more protection than is currently provided by § 102.5 While the agency is not persuaded that there is a consumer fraud problem with wild rice, it would certainly entertain a citizen petition to establish a specific common or usual name regulation if a proper case is presented that demonstrates that there is a problem and a regulation is needed.

IOM also concluded that the Georgia State requirement for Vidalia onions appears to be predominantly protectionist in that no specific justification is provided for limiting the source to the defined producing locality The agency concurs with IOM's assessment and, therefore, concludes that a specialized Federal common or usual name regulation for this product is not necessary Again, while FDA believes that § 102.5 adequately provides for the naming of this product, it would have no objection to the State of Georgia or any other group or industry submitting a citizen petition to FDA to establish a specific common or usual name regulation for Vidalia onion based on measurable geographical, botanical, or quality criteria that differentiates it from other varieties or species of onion.

With respect to fish, FDA has issued "The Fish List FDA Guide to Acceptable Market Names for Food Fish Sold in Interstate Commerce 1988" to provide acceptable market, scientific, and common names for a wide range of common species. The agency believes, as did IOM, that The Fish List provides order to the marketplace. FDA also has Compliance Policy Guides (CPG's) for "red snapper" and for surimi-based (minced fish) imitation crab and other fish substitutes (CPG 7108.04 and 7108.16, respectively). The agency believes that The Fish List and the various CPG's more than adequately protect the consumer from fraud, while establishing specific common or usual name regulations for the many species of fish would be beyond the agency's resources and would not result in an appreciable reduction in consumer fraud. Anyone who believes a specific common or usual name regulation is needed for a particular species of fish may, of course, submit a citizen petition with appropriate justification as to why such action is warranted.

Bottled water, honey, and oriental noodles were also cited by the comment as products examined by IOM. Oriental noodles have compositional requirements, and, therefore, any regulations promulgated by FDA for this product would be in the form of a standard of identity regulation. Food standards are promulgated under the authority of section 401 and 403(g) of the act, not section 403(i)(1). The agency further notes that it has issued a compliance policy guide for oriental noodles (CPG 7102.02: Chow Mein Noodles, Chinese noodles, and other Oriental Noodles; Labeling). The agency believes that the CPG for oriental noodles more than adequately protects the public from consumer fraud. Again, the agency would not object to any interested persons submitting a citizen petition to establish a standard of identity for oriental noodles. The agency notes that it is currently considering a citizen petition from the International Bottled Water Association requesting that FDA regulate bottled water The agency hopes to take action on this petition by the end of this year

Thus, FDA concludes that it does have a strong and adequate regulatory system in place to implement section 403(i)(1) of the act. Therefore, the agency accepts IOM's recommendation and rejects the comment on this point.

6. Section 403(k)—Declaration That the Product Contains Artificial Flavoring, Coloring, or Preservatives

12. One comment argued that section 403(k) of the act is not adequately being implemented because there are several areas where FDA's current regulations fall short. As examples the comment

noted that current regulations: (1) Do not require all artificial flavorings in foods to be specifically identified on the label by their common or usual name (the comment stated that artificial flavorings can be listed as "flavorings"), (2) do not give consumers that are sensitive to monosodium glutamate (MSG) or sulfites sufficient label information to be able to avoid these substances, and (3) do not require labeling to reflect the percentage of each type of ingredient (e.g., the term "natural and artificial flavoring" can be used for a product which has 5 percent artificial and 95 percent natural flavoring and vice versa) when both natural and artificial coloring and flavoring are used in a food.

The agency disagrees with the comment. The premise of the comment is based upon a faulty interpretation of the requirements of section 403(k) of the act, of the agency's implementation of those requirements, and of IOM's report. The issues being raised by this comment would require fundamental statutory changes.

With regard to the first point, although they are separate requirements, section 403(i)(2) and (k) of the act must be read together. Section 403(i)(2) of the act requires the listing of the ingredients of a food by their common or usual names except that spices, flavorings, and color additives not required to be certified under section 706(c) of the act may be designated as spices, flavorings, and colorings without naming each (see also section 403(g)). Section 403(k) of the act provides that a food shall be deemed to be misbranded if it bears or contains any artificial flavorings unless it bears labeling stating that fact. FDA has implemented and amplified the requirements of section 403(k) of the act in § 101.22(h), which provides that the label of a food to which a flavor is added shall declare the flavor in the statement of ingredients as "artificial flavor" or "natural flavor" or any combination thereof, as the case may be.

Thus, contrary to the comment's assertion, FDA does not have the legal authority to require that artificial flavorings be listed by their common or usual name. However, again contrary to what the comment asserted, FDA has required that artificial flavorings be designated by the term "artificial flavoring."

The agency notes that the comment's concerns about the need for sensitive individuals to have sufficient label information to be able to avoid substances such as MSG and sulfites and the lack of percentage labeling of artificial and natural flavorings when both are used in food are not germane to whether section 403(k) of the act is adequately being implemented. To the extent that MSG, sulfites, or other substances that cause food sensitivities are flavorings, section 403(k) of the act would not require that they be declared in a way that would permit consumers to avoid them. FDA regulations do require that sulfites that are present in detectable amounts are declared on the food label (see § 100.100(a)(4) and the document on ingredient labeling published elsewhere in this issue of the Federal Register), however, FDA adopted this requirement under other provisions of the act. Similarly, percentage labeling requirements are outside the scope of section 403(k) of the act, which requires only that the presence of artificial flavorings (or artificial colors or chemical preservatives) be declared on the label. Section 101.22(h)(1) of FDA's regulations set forth how the addition of both artificial and natural flavorings to a food is to be declared. Therefore, the agency rejects the comment on this point.

Having considered the comments, the IOM report and other available information, FDA finds that section 403(k) of the act is being adequately implemented.

D. Procedural Issues

13. One comment argued that the agency's failure to present more than a conclusionary acceptance of IOM's recommendations did not provide the agency's views on the decision as to which sections were adequately being implemented.

The agency disagrees. The agency explicitly stated its tentative conclusions as to those sections that were adequately being implemented, and those that were not, were based on the recommendations of IOM and all of the information that IOM supplied to the agency as a result of the contract between FDA and IOM (57 FR 33283 at 33285). The July 28, 1992, proposal announcing the proposed lists discussed in detail the approach taken by IOM and the criteria that it used to determine adequate implementation. The notice summarized the basis for IOM's recommendations with respect to each section of the act (57 FR 33283 at 33284 through 33285). All the comments and other information considered by IOM, along with its draft final manuscript and final report, were placed on public display for all interested persons to review.

FDA's presumptive tentative acceptance of IOM's recommendations was fully consistent with the 1990 amendments and with the Administrative Procedure Act. Section 6(b)(3)(A) of the 1990 amendments directs the agency to publish the proposed lists as determined under the contract with a public or nonprofit private entity, which turned out to be IOM. This is eactly what the agency did. Moreover, § 10.40(b) (21 CFR 10.40(b)), FDA's regulation that implements the Administrative Procedure Act on informal rulemaking, states that the proposal shall act out the terms or substance of the proposed action and summarize the facts and policy that underlie it. Again, the July 28, 1992, proposal fully complies.

Thus, the agency finds that it provided adequate notice for all persons interested in this rulemaking as to the basis for its tentative determinations of adequacy of implementation.

III. Economic Impact

FDA has examined the economic implications of the final lists as required by Executive Orders 12291 and 12612 and the Regulatory Flexibility Act. Executive Order 12291 compels agencies to use cost-benefit analysis when making decisions, and Executive Order 12612 requires Federal agencies to ensure that Federal solutions, rather than State or local solutions, are necessary. The Regulatory Flexibility Act requires regulatory relief for small businesses where feasible. The agency finds that this final rule is not a major rule as defined by Executive Order 12291. In accordance with the Regulatory Flexibility Act (Pub. L. 96–354), FDA has also determined that this proposed rule will not have a significant adverse impact on a substantial number of small businesses. Finally, because these lists implement a statute that provides for preemption of State and local laws in specified circumstances, FDA finds that there is no substantial federalism issue that would require an analysis under Executive Order 12612.

A. Alternatives

The primary alternatives available to FDA were as follows:

1 Accept recommendation of IOM report

2. Reject recommendation of IOM report

B Costs

1 Accept Recommendation of IOM Report

By accepting the recommendation of the IOM report, FDA is legally required to publish regulations that ensure that section 403(d) of the act is adequately implemented. The compliance costs imposed by FDA's acceptance of this

legal obligation depend on the regulations that FDA promulgates to fulfill this obligation. One possible regulation that FDA might promulgate simply repeats the language of section 403(d) of the act. The compliance cost of this regulation would be zero because section 403(d) is already legally binding on food package manufacturers. If more restrictive regulations are promulgated, then compliance costs may occur. Potential compliance costs to industry include designing and manufacturing new packages. FDA has estimated the cost of implementing the regulations in the proposal on misleading containers that is published elsewhere in this issue of the **Federal Register**.

2. Reject Recommendation of IOM Report

If FDA had rejected the recommendation of the IOM report, then FDA could have made one of the following decisions: (1) Find that all sections of the act defining circumstances in which a food is misbranded are adequately implemented, or (2) find that one or more sections of the act defining circumstances in which a food is misbranded other than section 403(d) are not adequately being implemented.

If all relevant sections of the act had been found to be adequately implemented, then compliance costs would have been zero. If one or more sections of the act defining circumstances in which a food is misbranded other than section 403(d) had been found to be not adequately implemented, then compliance costs may have occurred. One possible regulation that FDA might have promulgated in the latter case would have simply repeated the language of the relevant sections of the act. The compliance cost of this regulation would have been zero because these sections of the act are already legally binding on food package manufacturers. If more restrictive regulations are promulgated, then some compliance costs may be incurred.

C. Benefits

1. Accept Recommendation of IOM Report

By accepting the recommendation of the IOM report, FDA is legally required to publish regulations that ensure that section 403(d) of the act is adequately implemented. One possible regulation that FDA might promulgate simply repeats the language of section 403(d) of the act. The benefit of this regulation would be zero because section 403(d) of the act is already legally binding on food package manufacturers. If more restrictive regulations are promulgated, then there may be positive benefits. The potential benefit of more restrictive regulations would be a reduction in consumer dissatisfaction with the fill of food containers. FDA has estimated the benefits of implementing regulations in the proposal on misleading containers that is published elsewhere in this issue of the **Federal Register**.

2. Reject Recommendation of IOM Report

If FDA had rejected the recommendation of the IOM report, then FDA could have made one of the following decisions: (1) Find that all sections of the act defining circumstances in which a food is misbranded are adequately implemented, or (2) find that one or more sections of the act defining circumstances in which a food is misbranded other than section 403(d) of the act are not adequately being implemented.

If all relevant sections of the act had been found to be adequately implemented, then benefits would have been zero. If one or more sections of the act defining circumstances in which a food is misbranded other than section 403(d) had been found to be not adequately implemented, then there may have been positive benefits. One possible type of regulation that FDA might have promulgated in this case would have simply repeated the language of the relevant section of the act. The benefit of this type of regulation would have been zero because these sections of the act are already legally binding on food package manufacturers. Thus the benefits of this alternative would have been estimated to be zero. If more restrictive regulations had been promulgated, then there may have been positive benefits.

D. Conclusion

In accordance with Executive Order 12291, the agency has analyzed the economic effects of this proposed rule and has determined that this rule, if promulgated, will not be a major rule as defined by that order.

In accordance with the Regulatory Flexibility Act, the agency has considered the effect that this regulation would have on small entities including small businesses and has determined that this final rule will not have a significant economic impact on a substantial number of small entities.

The costs and benefits of this final rule depend on the regulations that FDA produces in response to the requirement that it promulgate regulations ensuring the adequate implementation of sections of the act that it finds are not adequately being implemented. The costs and benefits of those regulations will be zero if those regulations simply repeat the language of the relevant sections of the act. As noted above, the costs and benefits of implementing regulations are considered in the proposal on misleading containers.

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Final Lists

Based on its review of the IOM report, the comments to the July 28, 1992 proposal, and other available information, the agency is announcing its conclusions related to the adequacy of Federal implementation of sections 403(b), 403(d), 403(f), 403(h) 403(i)(1), and 403(k) of the act. FDA finds that the following sections are adequately implemented by FDA regulations: sections 403(b), 403(f), 403(h), 403(i)(1), and 403(k) of the act. Based upon the same considerations, FDA finds that section 403(d) of the act on misleading containers is not adequately being implemented by FDA regulations.

Having made these findings, FDA advises that section 403A(a)(3) of the act and section 6(b)(3)(B) of the 1990 amendments provide that no State or political subdivision of a State may directly or indirectly establish under any authority or continue in effect as to any food in interstate commerce any requirement for the labeling of food of the type required by sections 403(b), 403(f), 403(h), 403(i)(1), or 403(k) of the act that is not identical to the requirement of such section, effective February 5, 1993.

Published elsewhere in this issue of the **Federal Register** is a proposal entitled "Misleading Containers; Nonfunctional Slack-Fill," in which FDA is proposing revisions of its regulations to ensure adequate implementation of section 403(d) of the act. Upon the effective date of the final regulations based upon that proposal, no State or local subdivision of a State may establish or continue in effect any requirement that is not identical to the requirements of section 403(d) of the act and regulations issued thereunder. If the agency does not issue final regulations in response to the proposal by May 8, 1993, the proposed regulations will be

considered the final regulations under the 1990 amendments, and preemption will become effective on the effective date of the rules that, on May 8, 1993, are considered final rules.

Dated: November 5, 1992.

David A. Kessler,

Commissioner of Food and Drugs

Louis W. Sullivan,

Secretary of Health and Human Services.

BILLING CODE 4160–01–F

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

21 CFR Parts 20 and 101

[Docket No. 85N–0061]

RIN 0905–AB67

Food Labeling; General Requirements for Health Claims for Food

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is adopting general requirements pertaining to: (1) The use of health claims that characterize the relationship of a substance to a disease or health-related condition on the labels and in labeling of foods in conventional food form (conventional foods), and (2) the content of petitions regarding the use of such health claims pertaining to specific substances in such food. This action is being taken in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims for conventional foods. However, in the Dietary Supplement Act of 1992 (the DS Act), Congress imposed a moratorium on the implementation of the 1990 amendments with respect to dietary supplements with only very limited exceptions. Therefore, these final rules do not apply to dietary supplements of vitamins, minerals, herbs, or other similar nutritional substances. Elsewhere in this issue of the **Federal Register**, FDA is issuing final rules that respond, at least with respect to conventional foods and, to the extent that they would permit claims, with respect to dietary supplements, to the 1990 amendments' directive that the agency consider 10 topics associating substances with diseases or health-related conditions. Those final rules have been developed in accordance with the general principles of the requirements in this document.

EFFECTIVE DATE: May 8, 1993, except § 101 9(k)(1) which will become effective February 14, 1994, and §§ 101.14(d)(2)(vii)(B) and 101.14(d)(3) concerning restaurant firms consisting of 10 or less individual restaurant establishments for whom these sections will become effective on May 8, 1994.

FOR FURTHER INFORMATION CONTACT: Victor P Frattali, Center for Food Safety and Applied Nutrition (HFF–261), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–4064.

SUPPLEMENTARY INFORMATION:

I. Background

In the **Federal Register** of November 27, 1991 (56 FR 60537), FDA published a proposed rule to establish general requirements pertaining to: (1) The use of health claims that characterize the relationship of a substance to a disease or health-related condition on the labels and in labeling of both conventional foods and dietary supplements, and (2) the content of petitions regarding the use of such health claims pertaining to specific substances in food. The proposed rule was issued in response to provisions of the 1990 amendments (Pub. L. 101–535) that bear on health claims. With respect to health claims, the 1990 amendments amend the Federal Food, Drug, and Cosmetic Act (the act) by adding a provision (section 403(r)(1)(B) of the act (21 U.S.C. 343(r)(1)(B))) that provides that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition, unless the claim is made in accordance with section 403(r)(3) or (r)(5)(D).

Congress enacted the health claims provisions of the 1990 amendments to help U.S. consumers maintain healthy dietary practices and to protect these consumers from unfounded health claims. The House Report of June 13, 1990, states, "Health claims supported by a significant scientific agreement can reinforce the Surgeon General's recommendations and help Americans to maintain a balanced and healthful diet" (Ref. 1). Senator Orrin Hatch, one of the primary authors of the 1990 amendments, noted that diet has been implicated as a factor in the three leading causes of death (heart disease, cancer, and stroke) (Ref. 2). In addition, the statement of the House Floor Managers noted that "There is a great potential for defrauding consumers if food is sold that contains inaccurate or unsupportable health claims" (Ref. 3). The House Report characterized the need for regulation as "compelling" (Ref. 1).

FDA's first step in support of the congressional goals of the 1990 amendments appeared in the form of the proposed health claims regulation. The proposed regulation contained: (1) Definitions to clarify the meaning of specific terms used in the regulation; (2) preliminary requirements that a component of food must meet to be eligible to be the subject of a health claim; (3) a scientific standard for assessing the validity of claims both for dietary supplements and for conventional food, general labeling requirements for health claims that are permitted by regulation, and prohibitions on certain types of health claims; and (4) the required content of petitions for health claims.

In response to the proposed rule, FDA received over 6,000 letters, each containing one or more comments, from consumers, health care professionals, universities, State and local governments, foreign governments, trade organizations, consumer advocacy organizations, research institutes, industry, and professional organizations. In addition to receiving these written comments, the agency held a public hearing on January 30 and 31, 1992 (57 FR 239, January 3, 1992), on a number of food labeling issues, including the requirements for health claims. Some of the comments agreed with one or more provisions of the proposed rule without providing further grounds for support other than those presented by FDA in the preamble to the proposal. Other comments disagreed with one or more provisions of the proposed rule without providing specific grounds for the disagreement. A few comments addressed issues outside of the scope of the regulations and will not be addressed in this document. Most of the comments provided specific grounds in support of their positions concerning provisions of the proposed regulations. The agency has summarized and addressed the issues raised in the sections of this document that follow.

In October 1992, the DS Act was enacted. This statute states that, with certain limited exceptions, the Secretary (and FDA, by delegation) may not implement the 1990 amendments with respect to dietary supplements earlier than December 15, 1993. As a result, this final rule applies only to conventional food (Ref. 34). The DS Act establishes a timetable for the adoption of final rules implementing the 1990 amendments with respect to dietary supplements by December 31, 1993. One exception to the moratorium on the implementation of the 1990 amendments is a provision (section 202(b)) that states that FDA may, earlier than December 15, 1993, approve claims with respect to dietary supplements that are claims described in clauses (vi) and (x) of section 3(b)(1)(A) of the 1990 amendments. FDA is responding to this provision in the documents on the 10 specific substance-disease topics that accompany this final rule.

II. Definitions

FDA proposed definitions for "health claim," "substance," "nutritive value," and "dietary supplement" to serve as tools for clearly establishing the scope of the types of claims that would be

subject to the regulations promulgated under section 403(r)(1)(B) of the act. In addition, the agency proposed a definition for "disqualifying nutrient levels" to establish limits on the amounts of certain nutrients that are known to increase the risk of disease that can be in a food if that food is to bear a health claim in its labeling.

A. Definition of a Health Claim

As proposed, § 101.14(a)(1) stated:

Health claim means any claim made on the label or in labeling of a food, including a dietary supplement, that expressly or by implication, including "third party" endorsements, written statements (e.g., a brand name including a term such as "heart"), symbols (e.g., a heart symbol), or vignettes, characterizes the relationship of any substance to a disease or health-related condition. Implied health claims include only those statements, symbols, vignettes, or other forms of communication that a manufacturer intends, or would be likely to be understood, to assert a direct beneficial relationship between the presence or level of any substance in the food and a health or disease-related condition.

(56 FR 60537 at 60563)

As was explained in the preamble of the proposal (56 FR 60542), FDA derived this definition almost directly from the provisions of section 403(r)(1)(B) of the act. The proposed definition establishes that a claim must have at least two basic elements for it to be regulated as a "health claim." First, the claim must be about a "substance" as that term is defined in proposed § 101.14(a)(2). Secondly, the claim must characterize the relationship of the substance to a "disease or health-related condition." If a claim has one of these elements without the other, it would not be a "health claim," although it may still be subject to regulation under other provisions of the act (e.g., the requirement of section 403(a)(1) of the act that a label statement be truthful and not misleading).

Although FDA attempted in the proposed definition of a "health claim" to draw clear lines between health claims and other types of claims about diet and health, comments raised significant questions about the applicability of one or both of the elements highlighted in the definition. Many of these questions resulted because, at the time that it issued the proposal, FDA had not itself decided on the precise coverage of the definition. For example, in the proposal (56 FR 60537 at 60542), FDA stated:

While the act focuses on the substance-disease relationship, it is clear that the Congress was concerned about any disease claims that are made on food (Ref. 1). In reviewing the evidence on the 10 topic areas, however, FDA has become aware that there may be certain relationships between foods and diseases that are supported by the available evidence but that cannot be attributed to a particular nutrient. For example, the scientific evidence shows that diets high in whole grains, fruits, and vegetables, which are low in fat and rich sources of fiber and certain other nutrients, are associated with a reduced risk of some types of cancer. The available evidence does not, however, demonstrate that it is total fiber, or a specific fiber component, that is related to the reduction of risk of cancer. The question is thus whether, to fulfill Congress's intent in the 1990 amendments, FDA should regulate claims about apparent food-disease relationships and, if so, how it should do so.

In response to comments questioning the meaning of the proposed definition of a "health claim," the agency has sought to clarify this definition as well as the meaning of the terms "substance" and "disease or health-related condition."

B. Substance—The First Basic Element

As proposed, § 101.14(a)(2) stated:

Substance means a component of a conventional food or of a dietary supplement of vitamins, minerals, herbs, or other nutritional substances.

1. Some comments maintained that because section 403(r)(1)(B) of the act specifically addresses only a claim that characterizes the relationship of any nutrient required to be on the label of a food to a disease or health-related condition, claims about other types of nutrients or about foods are not subject to the provisions of section 403(r). Many of these comments contended that claims about foods and other types of claims must be controlled under the general regulatory regime that requires that a label be truthful and not misleading, and they maintained that FDA could not therefore require preapproval of such claims.

However, other comments stated that Congress intended to control claims about foods as well as nutrients. One comment pointed out that people do not eat nutrients as such; they eat foods that contain (or do not contain) those nutrients. Another comment advised that consumers would more readily understand claims about foods than about nutrients, and that where food claims were appropriate, consumers might be more likely to improve their diets. One comment stressed that FDA has historically defined "substance" expansively, asserted that this policy should not be changed, and suggested that the definition of "substance" should be consistent with the wording of § 170.3(g) (21 CFR 170.3(g)), which defines "substance" as including "a food or food component consisting of one or more ingredients." A few comments pointed out that an understanding of Congress' intent can be obtained by considering the legislative history of the 1990 amendments. One comment advised that, before the enactment of these amendments, Congress considered a great deal of testimony about how health claims should be related to an overall diet of various foods. For example, a representative from one professional organization told the House of Representatives in a hearing on the bill that ultimately became the 1990 amendments (Ref. 24) that health claims should be compatible with the dietary recommendations of the National Research Council's (NRC's) report "Diet and Health: Implications for Reducing Chronic Disease Risk" (the Diet and Health report) (Ref. 6). That NRC report recommends that people eat five or more servings per day of vegetables or fruits and increase their intake of starches and complex carbohydrates. This recommendation is tied to the conclusion that "Diets high in plant foods—i.e., fruits, vegetables, legumes, and whole-grain cereals—are associated with a lower occurrence of coronary heart disease and cancers of the lung, colon, esophagus, and stomach."

In addition, the comment stated that this theme was echoed by the American College of Physicians, which told the House in a prepared statement that the NRC, the Surgeon General, and other organizations "recommend a reduction in fat and an increase in complex carbohydrates and fruits and vegetables in order to reduce the risk of these cancers." Further, the comment advised that the Senate hearing held on November 13, 1989, before the Committee on Labor and Human Resources (Ref. 25), also included significant testimony about the overall health benefits of foods. For example, an official with the American Dietetic Association told the Senate that that organization supported the dietary recommendations of NRC and the Surgeon General, and that health claims should reflect those recommendations and "should assist the public to integrate specific food products into a well-balanced diet." Thus, the comment maintained that both the House and the Senate had before them a record in which various private and public health organizations endorsed the linking of health claims to foods consumed as part of an overall diet, an endorsement validated by repeated references to the dietary recommendations of the NRC and the Surgeon General, sources that FDA has considered authoritative.

Another comment stated that the congressional debates reveal an equal, if not a greater, concern for the health benefits of foods, as opposed to nutrients, and that this concern makes sense when one considers that many public and private health organizations recommend obtaining an adequate nutrient intake through the consumption of a variety of foods. The comment pointed out that it is clear that during the debates over the 1990 amendments, Congress drew no distinction between foods and nutrients. The comment cited a variety of statements from the Congressional Record to substantiate its contention. For example, the comment pointed out that Senator John Chafee of Rhode Island, cosponsor of S. 1425 (the Senate's version of the bill that became the 1990 amendments), said that the proposed legislation would provide definite guidelines governing "the claims and statements that can be made about food" (Ref. 26). Similarly, Senator Orrin Hatch of Utah, cosponsor of the Senate amendments to the House's version of the 1990 amendments, viewed the bill as covering health and diet-related claims about food products (Ref. 2).

FDA does not agree that section 403(r)(1)(B) of the act addresses health claims for only those nutrients required to be on the label of a food and does not include claims about other types of nutrients. The language of section 403(r)(1)(B) of the act is clear in that it pertains to a claim that "* * * characterizes the relationship of any nutrient which is *of the type* required by paragraph (q)(1) or (q)(2) to be in the label or labeling of a food * * *" (emphasis added). Section 403(q)(1) of the act lists specific nutrients that are required for food labeling as part of nutrition labeling. Section 403(q)(2) of the act permits the Secretary of Health and Human Services (the Secretary) to include by regulation any other nutrient not required to be listed by section 403(q)(1) if information about the nutrient will assist consumers in maintaining healthy dietary practices. Moreover, section 403(r)(5)(D) of the act relates to vitamins, minerals, herbs, or other similar substances. Thus, claims relating to a broad range of substances are potentially subject to regulation under section 403(r)(1)(B) of the act, and claims about a nutrient-disease relationship are not outside the coverage of section 403(r) simply because the nutrient in question is not required to be listed in the nutrition label. For these reasons, FDA is retaining the broader term "substance" in the regulations and will use it in this preamble.

In fact, FDA agrees with the comments that contended that the proposed rule interpreted the 1990 amendments too narrowly with respect to the regulation of claims about foods. The agency has reviewed the legislative history of the 1990 amendments and concluded that this history does indeed contain evidence to support the conclusion that Congress intended that foods could be the subject of claims that are regulated under section 403(r) of the act. However, this legislative history also makes clear that, to be subject to section 403(r) of the act, a claim about a food must be, at least by implication, a claim about a substance in the food. The House Report (Ref. 1) states:

> The requirement applies to any disease claim that is made with respect to required nutrients and other nutrients in food. However, a statement about the importance of good nutrition which does not make a direct or implied connection between any nutrient in the food and a particular disease is not necessarily a disease claim that will be covered by this section.

Thus when a consumer could reasonably interpret a claim about the relationship of a food to a disease or health-related condition to be an implied claim about a substance in that food, that claim would satisfy the first element of a health claim.

However, a claim about the benefits of a broad class of foods that does not make an express or implied connection to any of the substances that are found in foods that comprise that class would not constitute an implied claim. Such claims about classes of foods (e.g., fruits and vegetables) are not health claims because they are not about a substance.

Accordingly, FDA has revised the definition of "substance" in new § 101.14(a)(2) to include a specific food as well as a component of food. Although, the agency's tentative view is that the term "substance" has the same meaning regardless of whether the food is a conventional food or a dietary supplement that includes vitamins, minerals, herbs, or other nutritional substances, in response to the DS Act, FDA is not reflecting this view in the final regulation. FDA will decide whether to do so in the rulemaking it will undertake in response to the DS Act. For consistency with the revised definition of "substance," new § 101.14(d)(2)(vii) has also been revised, as explained in section V.E. of this preamble, to provide guidance for identifying the appropriate dietary intake of a specific food necessary to achieve the claimed effect.

FDA has not modified new § 101.14(a)(2) to be identical to § 170.3(g). However, new § 101 14(a)(2) and § 170.3(g) are fully consistent, and any differences in their wording reflect the different contexts to which they apply. The definition of "substance" in § 170.3(g) is specific to the definition of the term "food additive," and in that context it is appropriate because of the statutory definition of "food additive" as "any substance the intended use of which results or may reasonably be expected to result * * * in its becoming a component or otherwise affecting the characteristics of any food." (See section 201(s) of the act (21 U.S.C. 321(s))). Proposed § 101.14(a)(2) was drafted to reflect the broad coverage of section 403(r)(1)(B) of the act. Importantly, a substance under § 170.3(g) would also be a substance under new § 101.14(a)(2) and vice versa.

Under the revised definition of a substance that FDA has included in new § 101.14(a)(2), phrases on labeling such as "eat apples to ———," "eat low sodium foods to ———," "eat fruits high in fiber to ———," or "cook with garlic to———" would constitute references to a substance and would thereby satisfy one of the two essential elements of a health claim. However, phrases on labeling such as "eat a variety of foods to ———," "eat a variety of fresh fruits and vegetables to ———," or "follow the food pyramid to ———," without any reference, either express or implied, to a substance that might be in the foods, would not satisfy this element. The latter types of claims would not be subject to regulation as health claims. Of course, such claims would still be subject to the requirement in section 403(a) of the act that they be truthful and not misleading.

C. Disease or Health-Related Condition—Second Basic Element

As mentioned previously in this preamble, the proposed definition of "health claim" contains two basic elements, "substance" and "disease or health-related condition," that must be present for a claim to be a "health claim." FDA did not define the phrase "disease or health-related condition" in the proposal. This omission raised many questions and concerns in the comments.

2. Many comments objected that FDA's interpretation of the phrase "health-related" could be too broad. One comment was concerned that FDA might interpret the phrase to apply to statements pertaining to general good health. The comment noted that food itself sustains life, so the mere

identification of a product as a food is to that extent a "health-related" claim.

Another comment argued that such phrases as "invigorating," "relaxing," "stimulating," "feel better," "enjoy a good night's sleep," and "perform at your best" should be exempt from regulation because they do not refer to a disease. A few comments contended that claims about relationships between nutrients and the structure or function of the body (e.g., "this calcium fortified product helps build strong bones") should not be considered health claims.

Some of the comments suggested that the definition of a "health claim" should refer only to "disease" or "disease-related" claims because such a characterization more accurately reflects the nature of claims regulated by section 403(r)(1)(B) of the act. One comment asserted that the statutory phrase "a disease or health-related condition" does not set up two categories and maintained that the phrase "health-related" as used in the law appears to be nothing more than an expansion of the word "disease." The comment submitted a definition of the word "disease" from "Stedman's Medical Dictionary," (25th ed., p. 444, 1990), which states that a disease is "a morbid entity characterized by at least two of the following criteria: (1) Recognized etiologic agent(s), (2) identifiable group of symptoms, or (3) consistent anatomical alterations."

Although the legislative history of the 1990 amendments gives clear direction that Congress intended that health claims do include disease-specific claims, this history is not as explicit concerning what kind of claims are claims about a "health-related condition." As FDA pointed out in its response to the previous comment, Congress did, however, give clear direction that a statement about the importance of good nutrition that does not make a direct or implied connection between any substance in the food and a particular disease is not necessarily a disease claim that will be regulated as a health claim (Ref. 1). Thus, it is clear that Congress did not intend that all claims pertaining to general good health be considered health claims.

However, the inclusion of the phrase "health-related condition" in section 403(r)(1)(B) of the act in addition to the term "disease" leaves no question that Congress intended that claims about conditions other than diseases be regulated under this provision. Further, the legislative history of the 1990 amendments confirms this fact. In hearings before the Senate and the House of Representatives preceding the passage of the 1990 amendments, many references were made to two texts, the Diet and Health report by the NRC (Ref. 6) and "The Surgeon General's Report on Nutrition and Health" (the Surgeon General's report) (Ref. 5). In the former text (Ref. 6), a section entitled "Hypertension and Hypertension-Related Diseases" states the following:

> Deaths related to hypertension have been variously classified over recent years. They have either been considered as a separate entity or combined with such classes of atherosclerotic cardiovascular diseases as CHD and stroke. Thus, it is not useful to consider vital statistics alone in discussing the epidemiology of hypertension. Hypertension is treated here primarily as a risk characteristic of atherosclerotic cardiovascular diseases rather than a disease entity in itself.

Elsewhere in the Diet and Health report (Ref. 6), hypertension is defined as sustained, elevated arterial blood pressure measured by an inflatable cuff and pressure manometer. The text goes on to say:

> It [hypertension] has been clearly shown to increase the risk of developing stroke, coronary heart disease, congestive heart failure, peripheral vascular disease, and nephrosclerosis.

Further, the Surgeon General's report identifies high blood pressure as a common, chronic medical problem in the United States responsible for a major portion of cardiovascular disease. It then states that public health efforts have increased public awareness and knowledge of the risks and treatment of this condition (Ref. 5).

The repeated references in the legislative history to texts that place significant importance on the control of risk factors as a means of reducing the risk of disease persuades FDA that the agency should include such factors in any definition of a "health-related condition." In view of the explicitly stated intention of Congress to help Americans maintain a healthful diet (Ref. 1), Congress intended that the 1990 amendments facilitate communication to consumers of information about risk factors such as hypertension, which is a risk characteristic or factor for several diseases, including coronary heart disease and stroke. Accordingly, the agency concludes that the inclusion of "a health-related condition" in the coverage of section 403(r)(1)(B) of the act means that claims about risk factors related to disease, as well as claims about a disease, can be health claims.

Having reached this conclusion, FDA finds that one limitation on the coverage of the phrase "disease or health-related condition" is appropriate. The limitation is for claims about nutrient deficiency diseases. In the legislative history, Congress focused only on those health claims that related to chronic diseases affected by diet, such as cancer, heart disease, and osteoporosis. There is no indication that it intended to cover classical deficiency diseases (diseases resulting directly from a deficiency of a vitamin, essential mineral, or other essential nutrient). The relationships between nutrients and classical deficiency diseases are well-established. Moreover, such diseases are of little public health significance in this country. Under such circumstances, FDA believes that it would not be appropriate to subject such relationships to the health claims regime. Claims about such classical nutrient deficiency diseases are adequately regulated under the provisions of section 403(a) of the act and thus must be truthful and not misleading. However, as discussed in more detail further in this document, a claim about the benefits of vitamin D in preventing vitamin D deficiency, for example, would be misleading where the claim does not explain that few individuals in the United States are at risk of such a deficiency. Of course, some claims about such diseases may result in a product being regulated as a drug. Thus, claims about the administration of a nutrient either intravenously or nasally will be regulated as drug claims. This position is consistent with the position that the agency took in the February 13, 1990, proposal (55 FR 5176) with respect to nutrient deficiency diseases.

Therefore, to assist affected parties in clearly understanding what the second element of a health claim encompasses, FDA is adopting the following definition of "disease or health-related condition" in new § 101.14(a)(6):

> *Disease or health-related condition* means damage to an organ, part, structure, or system of the body such that it does not function properly (e.g., cardiovascular disease), or a state of health leading to such dysfunctioning (e.g., hypertension); except that diseases resulting from essential nutrient deficiencies (e.g., scurvy, pellagra) are not included in this definition (claims pertaining to such diseases are thereby not subject to §§ 101.14 or 101.70).

This definition does not differentiate between a "disease" and a "health-related condition." The two states are often so closely related that no bright-line distinction is practicable. Further, both states are regulated under section 403(r) of the act. Thus, there is no reason to separate one state from the other as long as both are covered.

FDA structured this definition primarily after the common sense definition of "disease" that appears in

the second edition of "Random House Dictionary of the English Language" (Random House, Inc., New York, NY, copyright 1987) without referring to examples of the causes of the dysfunctioning that were cited in that definition. For purposes of this rule, the agency did not pattern the definition after the one suggested in the comment because the clinical nature of the suggested definition would not be readily understandable. Thus, it is not suitable for use in a regulation.

The definition of "disease or health-related condition" would not generally encompass terms or phrases such as "invigorating," "relaxing," "stimulating," "feel better," and "perform at your best." Such terms would be covered under the regulatory regime of a label needing to be truthful and not misleading. Moreover, they may also subject the product to regulation under the structure or function of the body aspect of the "drug" definition (section 201(g)(1)(C) of the act). However, the definition would clearly encompass terms such as "osteoporosis," "heart disease," "cancer," and "high blood pressure."

For further clarification, the definition of "disease or health-related condition" is not considered by FDA to include a change in a biological parameter, such as a decrease in platelet (a type of blood cell that promotes blood coagulation) aggregation time or an increase in serum cholesterol, unless the parameter is associated with a disease or health-related condition, and there is evidence that altering the parameter can improve the condition. Of the two examples cited, high serum cholesterol is generally accepted as a predictor of risk for coronary heart disease, and there is evidence that decreasing high serum cholesterol can decrease that risk. For the health claim in new § 101.73, published elsewhere in this issue of the **Federal Register**, which associates dietary lipid intake with an increased risk of coronary heart disease, it may be appropriate, then, to permit as optional information a discussion of how dietary saturated fat, cholesterol, or both, affect blood cholesterol levels and, thereby, the disease that is the subject of the claim. Nevertheless, the agency considers it is inherently misleading for the claim to be articulated as an association between dietary lipids and serum cholesterol because of the potential to confuse consumers about the relevant disease for which the claim is authorized. It is not the biological indicator that is the disease or health-related condition for which the claim is authorized. Where there is no well-documented association or specificity between a biological parameter and a disease or health-related condition and some evidence that improving the parameter improves the condition, the agency will be disinclined to consider a petition for a health claim for that parameter because it fails to meet the definition of a disease or health-related condition.

3. Some comments asked if FDA intended to regard any statements that describe the "special dietary uses" of foods (e.g., hypoallergenic, lactose-free, wheat gluten-free, and dietetic foods) as health claims. The comments were concerned that health claim disqualifying levels would bar many such foods from disclosing dietary information. One of the comments requested that FDA revise the definition of a "health claim" to include advice that a statement in the labeling of a food subject to part 105 (21 CFR part 105) shall not be deemed to be a health claim solely because it represents the food to be for special dietary use.

FDA advises that any statement that appears on the label or in the labeling of a food intended for "special dietary use" that is consistent with provisions of the regulations promulgated under section 403(j) of the act will not be regulated as a health claim by the agency. Thus, such foods will not be subject to health claim disqualifying levels. However, FDA cautions firms that information not specifically provided for by specific regulations for foods for special dietary use may create an express or implied health claim and thereby subject such a food to the provisions of new § 101.14, including the disqualifying levels.

FDA has not revised the final rule to address foods subject to part 105 in the definition of "health claim." The requested revision is unnecessary in view of the agency advice in the previous paragraph. Further, the agency believes the requested revision might mislead some firms to assume that such foods would be exempt from the health claim provisions regardless of the nature of claims appearing in labeling where the claims are not specifically authorized in part 105. In addition, if FDA were to revise the final rule with respect to part 105, the rule should also be revised with respect to other provisions in the act and the regulations promulgated thereunder (e.g., infant formula subject to section 412 of the act (21 U.S.C. 350a)), and the agency does not believe that it would be appropriate to have the rule reference every other similar situation in the regulations in Title 21, Code of Federal Regulations.

D. Implied Health Claims

The agency proposed to define "implied health claim" as:

> * * * those statements, symbols, vignettes, or other forms of communication that a manufacturer intends, or would be likely to be understood, to assert a direct beneficial relationship between the presence or level of any substance in the food and a disease or health-related condition.

The agency then provided some examples of such claims—"third party" endorsements, written statements such as a brand name including a term such as "heart," and symbols such as a heart symbol.

1. General

4. Comments varied widely on whether FDA should regulate implied health claims. Some comments, noting the difficulty in specifically defining an implied health claim, suggested that implied health claims should not be regulated under the proposed regulations. One of these comments asserted that FDA could regulate implied health claims only under the general requirement that a label must be truthful and not misleading. However, other comments urged FDA to strictly regulate implied health claims because they have the potential to undermine the sound regulatory approach for explicit health claims.

FDA advises that there is no basis under the act for it not to regulate implied health claims. Regulation of such claims is specifically mandated. Under section 403(r)(1)(B) of the act, a food is misbranded if "* * * a claim is made in the label or labeling of the food which expressly *or by implication* * * *" (emphasis added) characterizes the relationship of any substance to a disease or health-related condition unless the claim is made in accordance with the health claims provisions of the act. Thus, FDA must reject the comments that suggested that it not regulate implied health claims.

5. While a number of comments encouraged FDA to take a broad view of what constitutes an implied claim, other comments argued that any "bright-line" definition of an implied health claim would be too inflexible to enforce fairly because labeling displays can have different meanings in different contexts. Some comments urged that both manufacturers' intent and consumer perception be considered in determining whether an implied claim has been made. One comment proposed that if vendor intent is not considered, then the test should be whether consumers acting reasonably under the circumstances would interpret language on labels or labeling in a particular

fashion and noted that such a test has been applied by the Federal Trade Commission (FTC) in the context of misleading advertising claims. The comment contended that the fact that a few credulous people may perceive a claim in a particular manner should not suffice if the vast majority perceive it otherwise.

FDA agrees that no "bright-line" definition can be established for implied health claims. Labeling claims need to be considered in their entirety and in context to determine if the elements of a health claim are present. FDA has therefore revised the definition of an implied health claim in new § 101.14(a)(1) to clarify that the claim will be evaluated within the context of the total labeling to determine if an implied health claim has been made.

FDA has also revised the list of the types of claims that may be implied claims. The agency has substituted the term "'third party' references" in place of the term "'third party' endorsements" because it has become clear that a third party endorsement is only one type of reference to a third party that may constitute a health claim in the context of the entire labeling. Further, FDA has corrected the phrase "health or disease-related condition" in the definition of an implied health claim in the last sentence in new § 101.14(a)(1) to "disease or health-related condition." FDA had intended to consistently use this latter phrase throughout proposed § 101.14(a)(1), but the terms "disease" and "health" inadvertently were interchanged in the proposal.

In the case of implied claims, FDA will evaluate all of the labeling to determine whether, within the context in which a claim is presented, both basic elements of a health claim are present. Where both elements are present in a product's labeling, the product bears a health claim, regardless of whether one or both of the basic elements are explicit or implied.

In making an evaluation of a claim within the context of the labeling, FDA agrees that it should consider both manufacturer's intent and consumer perception. However, the agency notes that intent means more than the manufacturer's subjective intent. Therefore, the agency concludes that the focus of its determination as to whether a claim is an implied claim should be on what the claim is saying. To be consistent with the definition of "implied nutrient content claim" in new § 101.13(b)(2) in the nutrient content claims document published elsewhere in this issue of the **Federal Register**, the agency is striking the phrase "* * * a manufacturer intends, or would be likely to be understood, to assert * * *" and is replacing it with the word "suggest" in the definition of a health claim in new § 101.14(a)(1). Section 101.14(a)(1) now reads:

Health claim means any claim made on the label or in labeling of a food, including a dietary supplement, that expressly or by implication, including "third party" references, written statements (e.g., a brand name including a term such as "heart"), symbols (e.g., a heart symbol), or vignettes, characterizes the relationship of any substance to a disease or health-related condition. Implied health claims include those statements, symbols, vignettes, or other forms of communication that suggest, within the context in which they are presented, that a relationship exists between the presence or level of a substance in the food and a disease or health-related condition.

The agency believes that this will clarify what the agency's inquiry will be when it determines whether a claim is an implied claim.

FDA has not used the comment's proposed "reasonable person" test for deciding when a claim is impled. The regulation reflects the fact that courts have construed the act as protecting not just the reasonable person but also the "ignorant, the unthinking and the credulous." (See *United States* v. *an article * * * consisting of 216 cartoned bottles * * * "Sudden Change,"* 409 F.2d 734, 741 (2d Cir. 1969).) Given relevant case law construing the act, it is unnecessary to look to the standard applied by FTC for guidance.

2. Brand names

6. A number of comments asserted that all brand names containing words such as "heart" are inherently misleading and therefore should be banned. Other comments urged FDA to permit the use of words such as "heart" in the brand names of foods only when the food qualifies for an approved heart-related health claim. Other comments maintained that some brands that incorporate the word "heart" (e.g., Sweetheart) have been used for decades in a nonmisleading manner to convey an old-time, homey feeling and therefore should not be banned or construed to be an implied health claim.

FDA does not agree that all brand names containing words such as "heart" are inherently misleading. Certainly where this term is placed on a product that qualifies for an express health claim on cardiovascular disease that is provided for in part 101, subpart E, and where such a claim is appropriately included elsewhere in the labeling, consumers would not be misled by the term "heart." In addition, there may be situations in which, when considered within the context of the full labeling, the term cannot be reasonably understood to be a health claim (e.g., "sweetheart" or "from the heartland of America," where no claims about the fat, cholesterol, or sodium content of the food are made).

However, comments from several consumer, health professional, and regulatory organizations demonstrate that the use of the word "heart" in the brand name of a food may lead consumers to believe that the specific food bearing that brand name has properties deriving from a substance that it contains that are beneficial for reducing the risk of developing a disease or health-related condition, specifically cardiovascular disease. Both basic elements of a health claim may be implied in a brand name containing the term "heart." Therefore, any product bearing such a brand name is subject, depending of course on the full content of the labeling, to be viewed by FDA as bearing an implied health claim. Thus, FDA has retained the term "heart" as an example of what may be an implied claim in the definition of "health claim" in new § 101.14(a)(1) to alert firms to the agency's position on this matter. However, FDA will review the context in which this term is presented and consider how the term would be understood in deciding whether a particular use of the term "heart" or a use of a heart symbol on a particular label is a health claim.

3. Other written statements

7. A number of comments suggested that any statement on a label, including nutrient content claims such as the word "healthy" or other terms that may lead consumers to believe that a food has health benefits, should be regarded as implied health claims. Comments suggested that FDA use broad latitude in considering such words as health claims.

As FDA advised earlier in this preamble, the agency will evaluate all of the labeling to determine whether, within the context in which a claim is presented, both basic elements of a health claim are present. Thus, FDA will take a flexible case-by-case approach to assessing whether labeling contains a health claim.

In the case of the word "healthy," the agency does not believe that the use of this word would normally be a health claim. "Healthy" has a wide variety of meanings in addition to ones that would satisfy the second basic element of a health claim. For example, "healthy" can certainly imply general nutritional well-being. Thus, while a claim such as "Eat a diet low in fat for a healthy heart" may be a health claim, "Eating

five fruits or vegetables a day is a good way to a healthy lifestyle" is not. Moreover, as explained in the document concerning nutrient content claims that appears elsewhere in this issue of the **Federal Register**, FDA may also regulate the term "healthy" in certain circumstances as an implied nutrient content claim. A proposal on how to define the term in such circumstances appears elsewhere in this issue of the **Federal Register**. The varied uses of the term "healthy" demonstrate the need for FDA to take a flexible case-by-case approach in deciding whether a claim is an implied health claim.

4. Third party references

8. Some comments requested that FDA explain its interpretation of the term "third party endorsement" and clarify when such an endorsement constitutes a health claim. One comment observed that the courts have been careful not to define the concept of "endorsement" too broadly and noted that disclaimers can be used where the perception of endorsement may be construed. Other comments asserted that the mere presence of endorsements should not automatically constitute health claims. One suggested that regulatory limits concerning such endorsements should be set.

FDA agrees that third party endorsements do not automatically constitute health claims. "Funk & Wagnall's Standard Dictionary," Harper Paperbacks, New York, 1980, defines the term "endorse" as "to state one's personal support of (a product) to promote its sale." FDA views third party endorsements as references, made through a name or logo, to a person or organization such as a professional society or association that is independent of the product's manufacturer or distributor, on product labeling or advertising, to promote that organization's approval of a product.

In response to the comments addressing the term "third party endorsements," as explained in the agency's response to comment 5 of this document, the codified language of new § 101.14(a)(1) has been revised to refer to "'third party' references." This term, which includes third party endorsements, better describes the type of information from an organization or individual not directly associated with the manufacturer that may be included in a label and that could constitute an implied or express health claim.

Third party references on food labels include a wide variety of information about diet and general health that is disseminated by reputable public or private organizations. Such information will be regulated as a health claim if, within the context of the total labeling, the third party reference can be reasonably understood to characterize the relationship between a substance and a disease or health-related condition. Thus, an endorsement by the American College of Nutrition or the National Nutritional Foods Association would not, of itself, cause a product to be considered to bear a health claim, even if these organizations were promoting the consumption of a specific food or nutrient, if the resultant claim did not include reference to a disease or health-related condition.

However, a third party endorsement would constitute an implied health claim if the endorsement references a particular food or substance, and the name of the endorsing organization references a particular disease (e.g., American Heart Association). In such an endorsement, both basic elements would be present. As a result, a link would be created between the food/substance and the specific disease that could be reasonably understood by consumers as asserting that the product is useful in reducing the risk of developing that disease.

The following illustration using the National Cancer Institute's (NCI's) Five-a-Day Program (Ref. 27) exemplifies how the context of the label will determine whether a statement is a health claim or dietary guidance. A cereal label that says "The National Cancer Institute recommends that you eat five servings daily of fruits and vegetables" is not a health claim because the information cannot be reasonably understood to be about a substance. There is neither a nutrient nor a product-specific element in the claim, and there is therefore no characterization between a substance and the disease included in the name or the organization. However, if the statement said "The National Cancer Institute recommends that you eat five servings daily of fruits and vegetables to increase your intake of fiber," it would be a health claim because of the reference to a specific nutrient, fiber, and to a disease, cancer.

9. Several comments questioned the status of the American Diabetes Association's "Exchange Lists for Meal Planning." One comment questioned the status of the American Diabetes Association's "Self-Test" public awareness program printed on the back of certain cereal boxes, which is designed to enable consumers to recognize diabetes based on warning signs and symptoms of the disease. The comments expressed the belief that these situations should not be interpreted as either an endorsement or a health claim because no claim is made about a specific nutrient in the foods, and no link is created between the products and diabetes. Comments also requested clarification of FDA's position on fund raising activities conducted with the cooperation of manufacturers using organizational logos and messages such as: "A proud sponsor of the American Diabetes Association" or "A contribution from the sale of this product has been made to the American Diabetes Association." The consensus of these comments was that these situations should not be interpreted as endorsements because no claim is made about the nutrient content of the foods, and there is no association between the products and the disease, diabetes mellitus.

FDA recognizes the value that providing exchange lists on food labeling has for certain consumers and advises that the mere inclusion of that information on a food will not, of itself, subject the labeling to the health claim regime. Reference to the exchange lists lacks the substance element of the "health claim" definition because it relates to many foods rather than to a specific food or a nutrient. Such information is instead subject to section 403(j) of the act and, more specifically, to § 105.67 relating to foods for use in the diets of diabetics. Of course, the labeling would be subject to regulation under section 403(r) of the act if the labeling bears any implication that a substance in the food is helpful in reducing the risk of diabetes or any other disease.

In the absence of an explicit or implied reference to a substance in food labeling, the "Self-Test" program and sponsorship/fund raising information also are outside the coverage of section 403(r)(1)(B) of the act. However, labeling for both of these programs would be subject to section 403(a) of the act, which requires that a label be truthful and not misleading, and section 201(n) of the act which describes the circumstances in which labeling is misleading.

10. Some comments requested that paid third party endorsements be prohibited. These comments stated that such references often give the public the impression that endorsed products are superior in terms of health, safety, or nutrition to other foods not bearing the same endorsement, when, in fact, they are not.

FDA has no authority under the act to prohibit either paid or unpaid third party endorsements or references, provided that, when such statements ar- included on food labeling, the

statements are made in a manner that is in compliance with all applicable provisions of the act. However, the agency recognizes that endorsements made for compensation by private organizations or individuals may be misleading to consumers. The agency is advising that when such endorsements are made, a statement should be included in close proximity to the claim, informing consumers that the organization or individual was compensated for the endorsement. Failure to divulge this information on a label that bears a paid endorsement would cause the product to be misbranded under sections 403(a) and 201(n) of the act for failure to reveal a fact that is material.

11. A number of comments suggested that all unpaid endorsements be regarded as explicit health claims.

FDA disagrees, because the issue of whether an endorsement is made in exchange for monetary compensation is not germane to the issue of whether the endorsement or other third party reference constitutes a health claim. As discussed in the response to comment 8 of this document, for a third party reference to be a health claim, two criteria must be met. There must be an implied or explicit reference to both a substance and to a disease or health-related condition. In the absence of these elements, a third party reference is not a health claim, regardless of any financial arrangement that may have been entered into before making the endorsement.

12. Other comments urged FDA to allow the use of third party endorsements of specific products. Many of these comments asserted that references from credible health organizations reduce or eliminate consumer confusion about specific products, provide useful and relevant information about products, and assist consumers in making healthy food choices. The comments also argued that the use of third party endorsements and references should also encourage the development of new products that attract such endorsements.

FDA has no basis in principle for objecting to the use of third party endorsements and other third party references for specific products, provided that such references are made in compliance with all applicable provisions of the act, including the nutrient content claims and health claims requirements of the 1990 amendments and sections 403(a) and 201(n) of the act. The agency is aware of the potential impact of the 1990 amendments on the development of more healthful products that will appeal to consumers and encourage people to improve their eating habits. In the Congressional Record of October 24, 1990, Senator Hatch (Ref. 2) stated:

> * * * manufacturers should have the economic incentives they need to be creative and innovative so that more and more low-fat, reduced sodium, and high-fiber foods come into the market. We should not deter such benefits for the consumer.

FDA is very much in favor of product innovation as a means of bringing more healthful products to the American public and recognizes that appropriate and lawful third party endorsements may have some potential to stimulate innovation and play a useful role in educating consumers about the importance of developing diets that will improve their health.

13. A number of comments recommended that FDA selectively designate which governmental and nongovernmental organizations are allowed to make third party endorsements. One comment suggested that FDA require organizations that grant endorsements to have the expertise in the area in question as well as a formal product approval process. The organization should actively disseminate additional explanatory information concerning the meaning of the endorsement and manner of its use. Other comments recommended that third party endorsements be considered to be misleading unless the reason for the presence of the endorsement is clearly explained (including but not limited to disclosure of financial arrangements).

With the exception of disclosing the fact that an endorsement has been paid for, as discussed in comment 10 of this document, FDA believes that it lacks the factual and legal basis at this time for imposing such requirements on third party endorsements. FDA recognizes, however, that third party references have significant potential to be abused or to be misleading if, for example, they come from organizations or programs that exist primarily for commerical or marketing purposes, they are not based on sound nutritional criteria, or they appear on products that are not appropriate in light of the actual or implied nutritional purpose underlying the endorsement. Therefore, the agency will closely monitor the use of endorsements on food labels. Interested persons should submit their views on the need for additional regulatory controls to the Center for Food Safety and Applied Nutrition. FDA intends to consider in a future rulemaking proceeding whether additional criteria or controls are necessary.

In the meantime, any labeling generated with a third party endorsement or reference would be subject to regulation under sections 201(n) and 403(a) of the act and must, therefore, be truthful and not misleading. Further, if the reference meets the definition of a nutrient content claim or a health claim, such a claim must be consistent with FDA's regulations.

14. A number of comments suggested that all written health claims be banned in favor of third party endorsements. One of the comments favored allowing third parties, such as the American Heart Association and the American Dental Association, to independently review products and to place their logos on the labeling if they determine that use of the product would be helpful in reducing the risk of their specialty disease.

FDA has an obligation under the act to ensure that health claims comply with section 403(r) of the act, and that they are truthful and not misleading under section 403(a). Delegation of this responsibility to private organizations associated with specific diseases would not be consistent with the act. Such organizations are free to submit well-supported petitions pertaining to the health benefits of any substance to FDA, as provided for in new § 101.70. However, FDA will always have the obligation of ensuring compliance with the act.

5. Symbols

In the preamble to the proposed rule (56 FR 60537 at 60542), FDA recognized that there is often ambiguity in the message conveyed by a symbol or logo and solicited comments on the appropriate meaning to be attributed to a heart symbol and other currently used logos and symbols. The agency also invited comments on the issue of how logos should be regarded: as nutrient content claims, health claims, or both? The comments, which are summarized below, ranged from those that wanted strict regulation of symbols to those that felt symbols should not be regulated as health claims. Many comments took an intermediate position, arguing that symbols should be evaluated within the context of total labeling.

15. Many comments supported FDA's proposal to regulate symbols as health claims. These comments stated that the uncontrolled use of medical symbols (e.g., a heart or an electrocardiogram (EKG)) should not be permitted. Some comments suggested that symbols be allowed only when the food qualifies for the health claim implied by the symbol, and then only if they are not misleading

and increase consumers' comprehension of the claim.

Many industry comments argued that symbols cannot practicably be included in the definition of a health claim. One comment pointed out that candy packages bearing a heart symbol near Valentine's Day should not be regulated as an implied health claim. Another comment cited examples where the heart symbol may do nothing more than operate as a design motif with no implicit health claim (e.g., the combination of a heart symbol plus the statement "Hey Fudge Lovers! More Fudge Filling!"). The comments maintained that any analysis of how the symbol is construed must focus on the entire label, not on an isolated aspect of it.

FDA agrees that a determination as to whether a symbol constitutes a health claim must be made based on the entire food label. As explained in the response to comment 5 of this document, FDA has provided for such flexibility by revising new § 101.14(a)(1) to state:

> Implied health claims include those statements, symbols, vignettes, or other forms of communication that a manufacturer intends, or that would be reasonably understood in the context in which they are presented, to assert a relationship between the presence or level of a substance in the food and a disease or health-related condition.

"Funk & Wagnall's Standard Dictionary" defines the term "symbol" as "something chosen to represent something else; esp., an object used to typify a quality, abstract idea, etc." Determining whether a symbol on a label represents an implied health claim requires an evaluation of all of the labeling to ascertain whether, within the context of that labeling, the presence of that symbol results in both basic elements of a health claim being present in the labeling.

Because of the abstract nature of symbols, they have considerable potential for conveying a wide variety of meanings on labeling. As the comments pointed out, the same symbol on a food label may have a multitude of meanings for the same food as the context of the labeling is changed from one label to another. Certainly, the combination of a heart symbol and the statement "Hey Fudge Lovers!" on a food containing fudge adequately explains the meaning of the heart symbol and prevents consumers from being misled about its meaning. Under such circumstances, the heart symbol would not convey either of the basic elements of a health claim. The statement "Hey Fudge Lovers!" clarifies that the symbol does not refer to a substance in the specific food bearing the symbol or to any health benefits from consuming that food.

However, if the statement "Hey Fudge Lovers!" does not appear on the product, and no other explanation of the heart symbol appears on the labeling, the context of the labeling no longer explains the meaning of the symbol. Under such circumstances, the symbol may well be perceived by consumers in a wide variety of ways, many of which would not be true. FDA believes that most of the perceptions about heart symbols fall under the regulatory regime of a health claim. For example, consumers may logically assume that the symbol is equivalent to the term "heart." Under such circumstances, these consumers may conclude that the symbol means that the food has properties that are beneficial for reducing the risk of developing a disease or health-related condition, specifically cardiovascular disease. Thus, the second basic element (i.e., disease or health-related condition) would be conveyed by the symbol. Further, the first basic element (i.e., substance) would also be present. In the absence of an explanation for the symbol, consumers would likely infer that the symbol pertains to the specific food bearing the symbol and to the substances that it contains. Thus, both basic elements of a health claim can be implied through the unexplained presence of a heart symbol on a label.

Even if the heart symbol is not perceived by some as a health claim, the symbol would still be misleading within the meaning of section 403(a)(1) of the act because the context of the labeling would not explain what the symbol means and thus would fail to disclose a material fact. Accordingly, FDA advises that the use of health-related symbols in food labeling without some clarification of their meaning in context is likely to cause the food to be misbranded.

Similarly, an EKG (a record of the electrical current produced by the action of the heart muscle) also constitutes a health claim where the context of the labeling does not explain the meaning of the EKG. Although it is unlikely that most consumers would be able to interpret an EKG reading as representing a healthy or unhealthy heart, most consumers would probably make a connection between an EKG graph and heart function. Under such circumstances, the symbol alone could lead consumers to believe that a substance in the product is related to the risk of cardiovascular disease and thereby constitute a health claim.

Of course, symbols with specific reference to nutrients may also constitute health claims. For example, a heart on a label that also makes a claim that the product is low in fat would be an implied health claim. The explicit nutrient content claim would satisfy the substance basic element, and the disease or health-related basic element would be provided by the symbol because it implies that the low level of fat has a beneficial effect relative to a disease of the heart. (This decision assumes the label does not contain sufficiently clarifying information to change the meaning of the heart symbol, so that the symbol would not constitute a basic element.)

However, in some circumstances, the context of the labeling may make it obvious that there is no connection between the symbol and a substance in the food or between the symbol and a disease or health-related condition. In such a situation, the symbol would not constitute an implied claim. For example, a heart shaped box of candy or a heart shaped candy, whose label does not include an explicit or implied reference to a disease or health-related condition, would not be an implied claim.

In addition, some symbols, such as the U.S. Department of Agriculture/Department of Health and Human Services (USDA/DHHS) Health Pyramid, a symbol for the American Heart Association, or a symbol for the American Cancer Society, may not constitute health claims when the labeling contains no other references to a substance or a disease or health-related condition. In all of these situations, the organizations provide general dietary guidance for good health. Thus, consumers should not assume from the name of the organization that the symbol implies an association with the disease or health-related condition basic element.

When symbols constitute a health claim, they should only be used on foods that qualify for the express claim they represent. Since it is unlikely that a symbol alone can convey all the information necessary as part of a health claim, health claims implied by symbols must be accompanied by a written message that includes the essential elements of the claim authorized by FDA's regulations in part 101, subpart E. To prevent misinterpretation of the claim by consumers, this message should be located in close proximity to the symbol but could be located in other labeling provided that a reference statement appears next to the symbol. The appropriate content of health claims reference statements is discussed subsequently in section V.C. of this preamble. FDA has revised the

provision of the final rule addressing reference statements in new § 101.14(d)(2)(iv) to provide that such statements shall appear in immediate proximity to the graphic material (e.g., symbol). Anyone wishing to use a symbol alone to deliver a health claim may submit a petition with supporting data that demonstrate that the essential elements of the health claim are conveyed to consumers by the proposed symbol.

FDA recognizes that symbols are an important means of conveying information to consumers, and that they are useful when used in a truthful and nonmisleading manner. The agency will continue to protect the interests of the public by monitoring the use of symbols and will take appropriate action under either section 403(a) or (r) of the act when symbols are used to mislead consumers.

16. Some comments proposed that, if symbols such as a heart are to be regulated as implied health claims, products that bore such symbols before the implementation of the regulation should be exempted from the health claims regime.

Although the statute provides very explicit guidance regarding grandfathering of nutrient content claims in sections 403(r)(2)(C) and (r)(2)(D) of the act, it is silent with respect to any such provision regarding health claims. In light of this omission, it is clear that Congress did not intend to provide such relief for labeling making either implied or explicit health claims (see *Andrus* v. *Glover*, 446 U.S. 608 (1980)). Further, grandfathering of labels that do not qualify to bear an implied health claim would result in confusion on the part of consumers and reduce the credibility of symbols on food labels that are eligible to bear such claims. Therefore, FDA is rejecting this proposal.

17. Several comments suggested that the final rules should make some provision for the use of FDA standardized symbols and logos on products that would qualify for health claims. The comments stated that such logos and symbols would help individuals with poor reading skills plan a more healthful diet, although they did not make clear whether the use of symbols and logos should be optional or mandatory.

As stated above, FDA recognizes the value that symbols and emblems have in promoting good health and dietary guidelines to consumers. However, at this time the agency feels that it is inappropriate to permit an emblem alone to deliver the substance of a health claim, and it would be difficult for FDA to design standardized symbols or logos in a manner that would be in compliance with the statute. Section 403(r)(3)(B)(iii) of the act requires that a health claim be accurate and comprehensible within the context of the daily diet. New § 101.14(d)(2)(iii) requires the inclusion of factors other than consumption of the substance when such factors affect the substance-disease relationship (e.g., exercise).

Further, under section 201(n) of the act, labeling can be misleading based on what is omitted as well as on what appears on the label. Designing an emblem that would deliver the message required by the act while also meeting the criterion of being truthful and not misleading, as mandated by section 403(a)(1) of the act, would be extremely difficult.

However, the agency will consider petitions for use of a symbol or emblem for approved claims or as part of a new health claim petition, provided that appropriate data are submitted that provide the agency with some assurance that consumers accurately interpret the claim. Such data should include the results of tests using the suggested symbol.

6. Dietary guidance

As FDA explained earlier in this preamble, when the proposal was issued, FDA had not yet decided how certain types of claims should be regulated when they pertain to truthful information about health and diet and are not in the form of an explicit health claim. FDA referred to "dietary guidance" as a class of claims that might not be regulated under section 403(r) of the act. The agency cited the NCI "Five-A-Day" program as an example of dietary guidance that is not a health claim. Unfortunately, use of that program as an example created confusion because, even though most of the messages in the program only encouraged consumers to eat fruits and vegetables, a small number of the messages refer to nutrients (e.g., fiber) and disease (cancer).

Further, use of the term "dietary guidance" to describe claims that do not constitute "health claims" is also confusing because "health claims" themselves provide a form of dietary guidance. In addition to "health claims" and "dietary guidance," there is a broader class of claims that encompasses all other truthful information about diet and health as well as drug claims. In view of the overlapping nature of these categories of claims, it is understandable that there was considerable confusion among the comments about "dietary guidance."

For the sake of clarity in this preamble, FDA will use the term "dietary guidance" to refer to claims that do not contain both basic elements of a health claim and are therefore not "health claims." However, use of this term in the comments may, or may not, have encompassed a "health claim." FDA will attempt to clarify the use of the term by the comments in the summaries to the comments.

18. Some comments asserted that dietary recommendations that relate to a specific disease but provide guidance concerning general food choices without unduly emphasizing a particular substance, or recommendations that emphasize a particular substance but are related to a variety of diseases or to a healthy lifestyle in general, should not constitute implied health claims.

As discussed in the response to comment 1 of this document, claims that do not satisfy either the substance element or the disease or health-related condition element of the "health claim" definition are not health claims. Accordingly, claims that provide guidance about a general food choice or about how to achieve a healthy lifestyle would not be health claims. Claims that are related to a variety of diseases are likely to be health claims, although a specific determination will be made based on the context in which a claim is made and on its specific content.

19. A number of comments contended that the agency unjustly regulated accessibility to recommendations from authorities, such as the National Institutes of Health and USDA. Most comments felt that such dietary guidance should not be regulated as health claims on food labeling because such regulation would discourage education of the public on sound nutrition practices. One comment suggested that the furtherance of consumer information was mandated under the 1990 amendments and asserted that industry and FDA need to focus more attention on the education authority provided therein. This comment and others stated that public health organizations, such as NCI, can more effectively reach consumers with valuable advice if products that fit into their recommendations are free to display this information on their labels, and that consumers are more likely to notice and appreciate recommendations from a respected source. Other comments felt that nongovernmental sources (e.g., the American Dietetic Association and the American Heart Association) also provide credible dietary guidance.

FDA has reconsidered the tentative position that it took in the proposal (56

FR 60537 at 60555) that references to programs sponsored by such organization as the American College of Nutrition, the American Heart Association, the American Medical Association ("Campaign Against Cholesterol"), and the American Medical Women's Association would always be regulated as implied health claims. The comments have convinced the agency that it would not be appropriate to establish by regulation the specific types of statements that may be used on food labeling concerning either Federal programs or private sector programs because the guidance offered by such organizations may not include a reference to a substance or to a disease or health-related condition. The agency has therefore concluded that publicly available dietary information provided to consumers by Federal or private programs and used in food labeling by manufacturers may be either dietary guidance or a health claim depending upon the content of the information and the context in which it is presented in the labeling.

In taking this position, FDA hopes to encourage the dissemination of information to consumers regarding nutrition and health that has been provided by such sources as the U.S. Surgeon General, the National Academy of Sciences, USDA/DHHS Dietary Guidelines, NRC, and the National Cholesterol Education Program. However, information from such programs presented in labeling in a context that includes explicit or implicit references to both elements of a health claim is subject to the health claims provisions of the act.

20. Many consumers asserted that dietary supplements, including supplements containing herbs, should be permitted to include all types of nutritional and dietary guidance in their labeling, including information based on folklore and historical use, provided that the claims are made truthfully. These comments maintained that such information is essential to making informed choices of such alternatives to conventional drug therapies.

Manufacturers of dietary supplements are free to provide dietary guidance within the regulatory framework discussed above. However, if a product's labeling characterizes the relationship between a disease or health-related condition and a substance, the product will be subject to the provisions of section 403(r) of the act, although in the case of dietary supplements they will not be subject to section 403(r) of the act until the expiration of the moratorium established by the DS Act. If the claim reveals that the product is intended to be used in the diagnosis, cure, mitigation, treatment, or prevention of a disease, the product, like any other product that does so, is a drug under section 201(g)(1)(B) of the act. When the moratorium expires, and subject to the regulations in place at that time, supplement and herb manufacturers, like all other food manufacturers, will be welcome to submit health claim petitions that establish the validity of claims that characterize the relationship of a substance to a disease or a health-related condition.

E. Definition of Nutritive Value

21. A number of comments asserted that FDA's definition of "nutritive value" in proposed § 101.14(a)(3) is unduly restrictive and does not fully recognize the important role that nutrients play in helping to reduce the risk of chronic disease. Other comments requested that FDA state in the definition that the list of processes cited is not all-inclusive. Another comment asked that the proposed rule be modified to specifically recognize the nutritive value of fat substitutes (triglycerides and other substances that contain fatty acids but are modified in ways that limit the bioavailability of those acids).

FDA recognizes that certain substances can play a major role in reducing the risk of certain chronic diseases and may confer their benefits through a number of processes. Accordingly, the agency has worded the definition of "nutritive value" in new § 101.14(a)(3) to provide significant flexibility in determining whether a substance possesses such value. FDA used the phrase "such * * * as" in the definition to insure that the three referenced processes will be understood to be general examples of the ways in which a substance may legitimately confer nutritive value, rather than as an all-inclusive list.

The agency believes that it is inappropriate to codify findings of nutritive value for specific substances. Such findings would only serve to undermine the intended flexibility of the definition because an extended listing of those substances that possess nutritive value could be interpreted as an exclusive list.

FDA considers it more appropriate for the agency to evaluate the nutritive value of substances that are the subjects of health claim petitions on a case-by-case basis. This approach will best ensure that the definition retains its intended flexibility and does not become an unintentional barrier to the approval of legitimate health claims.

F. Definition of Dietary Supplement

22. A number of comments suggested that the proposed definition of "dietary supplement" in proposed § 101.14(a)(4) should be revised to include foods as well as components in foods (e.g., herbs as well as components in herbs).

FDA advises that the proposed definition of "dietary supplement" already covers foods. Reference to a "component" with nutritive value encompasses the specific portion of the food, that is, of the dietary supplement, responsible for this value. Under section 201(f)(3) of the act, a component of a food is itself a food. However, because of the provisions of the DS Act, FDA is not adopting § 101.14(a)(4) at this time. FDA will reach a final decision on the appropriate definition of this term following in accordance with the provisions of the DS Act.

G. Definition of Disqualifying Nutrient Levels

As proposed, "disqualifying nutrient levels" was defined in proposed § 101.14(a)(5) as:

Disqualifying nutrient levels means the levels of total fat, saturated fat, cholesterol, or sodium in a food above which the food will be disqualified from making a health claim. These levels are 11.5 grams (g) of fat, 4.0 g of saturated fat, 45 milligrams (mg) of cholesterol, or 360 mg of sodium, per reference amount commonly consumed, per label serving size, and per 100 g. Any one of the levels, on a per reference amount commonly consumed, a per label serving size or a per 100 g basis, will disqualify a food from making a health claim.

For consistency with the final rule on serving sizes published elsewhere in this issue of the **Federal Register**, the word "commonly" in the term "reference amount commonly consumed" in the definition above is corrected to read "customarily."

1. Consistency with statute

23. Most industry comments contended that the proposed definition of "disqualifying nutrient levels" in proposed § 101.14(a)(5) is either overly restrictive or inconsistent with the statutory provision of section 403(r)(3)(A)(ii) of the act. The comments based their arguments on the language of the provision that provides that a health claim cannot be made by a food that contains "any nutrient in an amount which increases * * * the risk of a disease or a health related condition." Several comments stated that the agency correctly acknowledged that there are no generally recognized levels at which nutrients in an individual food pose an increased risk of disease, although there are

recommended levels associated with decreased risk of disease for dietary intake of total fat, saturated fat, cholesterol, and sodium. A number of these comments argued that the acknowledgment by FDA of a lack of recognized risk levels in an individual food should prevent the agency from establishing any disqualifying nutrient levels because the 1990 amendments require FDA to consider whether the individual food for which the claim is made contains a nutrient at a level that increases to persons in the general population the risk of a diet-related disease, taking into account the significance of the food in the total daily diet.

The comments argued that single foods, even when their significance in the total daily diet is considered, do not increase disease risk because only total diets consisting of many foods consumed over time have that potential. Thus, these comments argued that FDA cannot reasonably take the position that the analysis upon which the proposed disqualifying levels are based constitutes a credible scientific determination that the specific levels are the levels that, if exceeded in an individual food, increase the risk of disease in the general population. Other comments stated that if the agency believes that it has in fact determined levels that will increase the risk of diet related disease when present in individual foods, then either the marketing of such foods should be disallowed under the act by virtue of their being injurious to health under section 402(a)(1) of the act (21 U.S.C. 342(a)(1)), or warning labeling should be required on all foods containing such levels regardless of whether they contain health claims.

Some comments asserted that Congress intended for FDA to disallow a health claim on the basis of disqualifying nutrient content only if there exists an actual risk as determined by the analysis of actual consumption data for the specific food, and not as determined from models based on theoretical diets and extrapolation. Therefore, these comments argued that disallowing health claims on the basis of theoretically-derived nutrient disqualifying levels is contrary to the legislative intent of section 403(r)(3)(A)(ii) of the act, which reads, "If the Secretary determines * * *" and not "The Secretary shall determine * * *." These comments maintained that FDA had failed to show that a person exposed to foods with levels of fat, saturated fat, cholesterol, and sodium above the disqualifying levels were actually at an increased risk for various diseases and maintained that such an actual risk must be shown for FDA to legally establish disqualifying levels for these nutrients.

One comment noted that FDA's proposed model health claims emphasize the role of the total diet in reducing the risk of various diseases and do not allow manufacturers to claim that an individual food will reduce the risk. The comment stated that it was ironic and inappropriate, then, that FDA would single out individual foods as increasing the risk of those same diseases, and set disqualifier levels for those foods. Other comments agreed, saying that an individual food could no more cause a disease than prevent one.

FDA disagrees that the 1990 amendments require that FDA consider whether the individual food for which the claim is made contains a nutrient at a level that increases to persons in the general population the risk of a diet-related disease. There is nothing in the legislative history of the 1990 amendments that would support such a contention. To the contrary, the legislative history and the language of the statutory provision that ultimately resulted suggest that Congress intended that the risk of diet-related disease be considered in a far broader context than that of an individual food. Section 403(r)(3)(A)(ii) of the act states that the risk of a disease or health-related condition be considered "* * * taking into account the significance of the food in the total daily diet * * *." Thus, FDA must consider the role that a particular food plays in the total diet, and the effect that its nutrient levels will have on a person's ability to structure a healthy diet in making a determination under section 403(r)(3)(A)(ii) of the act. That provision contains no language implying that risk should be considered in terms of the immediate impact of consuming the particular food at issue.

Further, if Congress had been concerned about the impact of consuming a nutrient in a particular food, it would not have provided an exemption to disqualification in section 403(r)(3)(A)(ii) of the act when FDA finds that a claim will assist consumers in maintaining healthy dietary practices. Under the comment's view of this provision, no such circumstances could exist. Similarly, Congress would not have elected to provide for nutrient content claims with only disclosure requirements for such nutrients in section 403(r)(2)(B) of the act if the risk from a particular food was the concern that it was addressing. Further, if risk from a particular food was its concern, Congress would not have exempted nutrient content claims on restaurant foods from these disclosure requirements (see section 403(r)(5)(B) of the act).

Congress intended that health claims would not merely provide information on particular substance-disease relationships, but that they would help individuals to maintain healthy dietary practices. The House Report (Ref. 1) states:

> * * * Health claims supported by significant scientific agreement can reinforce the Surgeon General recommendations and help Americans to maintain a balanced and healthful diet * * *.

Health claims on foods with levels of fat, saturated fat, cholesterol, or sodium that exceed the disqualifying levels will make it much more difficult for consumers to follow the Surgeon General's recommendations and to construct a healthy diet. An increase in risk in a diet-related disease follows as a result. All references in the legislative history concerning the meaning of section 403(r)(3)(A)(ii) of the act show that Congress was concerned with general levels of nutrients in broad food classes that could increase risk rather than levels of nutrients that could increase risk from individual foods. For example, the House Report (Ref. 1), in addressing the meaning of this provision, states:

> By requiring the Secretary to decide this issue in the total daily diet, the bill permits the Secretary to differentiate between different foods which have the same level of a nutrient. For example, a particular level of fat in a frozen dinner might not trigger the provision [disqualification], whereas the same amount of fat in a snack food product might trigger it.

Further, in testimony presented before the House of Representatives on a predecessor bill to the 1990 amendments (Ref. 24), a consumer organization identified ways by which health claims on products in the U.S. marketplace can deceive consumers. One such way was for a product to highlight a characteristic that may help reduce the risk of a disease but remain silent about another characteristic that may affect the risk of the same, or another, disease. An example cited in the testimony was a breakfast cereal bearing a health claim approved by NCI on the association between dietary fiber and cancer while containing 4 g of fat per serving—an amount characterized as quite high for a breakfast cereal. In testimony presented before the Senate on a predecessor Senate bill to the 1990 amendments (Ref. 25), another consumer organization stated that a health claim on a product must provide consumers with the assurance that the

product does not also contain properties that are potentially harmful to health. The testimony continued:

> But a health claim on whole milk, promoting its calcium content [relative to osteoporosis], could encourage consumption of a product high in saturated fat. Low-fat milk has all the benefits of whole milk, without the accompanying risks, and would be a more appropriate vehicle for health claim labeling.

Congress obviously recognized the fact that, as pointed out in some of the comments, single foods, when their significance in the total daily diet is considered, do not generally increase disease risk. It is the total diet, consisting of a number of foods consumed over time, that has the potential to increase disease risk. Thus, FDA believes that the purpose of section 403(r)(3)(A)(ii) of the act is to ensure that FDA establishes appropriate disqualifying levels for those nutrients that have the potential, at high levels of consumption, to increase disease risk so that consumers who rely on health claims will be consuming foods that will assist them in meeting dietary guidelines in constructing their total daily diet, and not foods that make it more difficult to do so.

FDA also does not agree that Congress intended that section 403(r)(3)(A)(ii) of the act only prohibit health claims where the level of risk from a nutrient is sufficient to invoke the adulteration provisions of the act. Disqualifying levels in no way should be construed as nutrient levels that FDA believes are harmful in an individual food. The House Report (Ref. 1) explains that this provision pertains to nutrients required to appear on the label and specifically points out that certain levels of fat in foods may trigger this provision. Foods that are 100 percent fat are still safe and lawful under the act. FDA believes that fat was cited to make it obvious that the provision is intended to provide a measure of control for diet-related diseases that are influenced by excessive consumption of safe and lawful nutrients.

In appropriate amounts, such nutrients have a necessary or useful place in the total daily diet. In fact, where the only safety issue is an increased risk of a chronic disease from excessive consumption, the safety provisions of the act would not provide regulatory sanctions against such components of foods, at least if they have not been added to foods. For such components, FDA must show that the component is a poisonous or deleterious substance that would ordinarily render the food injurious to health. If Congress had intended that section 403(r)(3)(A)(ii) of the act to prohibit health claims only where the level of risk from a nutrient is sufficient to invoke regulatory sanctions, the provision would have been unnecessary. Clearly, Congress had something else in mind.

The agency also disagrees with the comments that argue that FDA developed disqualifying nutrient levels based on a misconstruction of the statutory language and intent of section 403(r)(3)(A)(ii) of the act. That section does not read, as one comment stated, that disqualifying nutrient levels may be established * * * "if the Secretary determines * * *." Instead, it states that a health claim may only be made "* * * if the food for which the claim is made does not contain, as determined by the Secretary by regulation, any nutrient in an amount that increases to persons in the general population the risk of a disease or health-related condition which is diet related * * *." FDA believes that the most straightforward reading of this provision is as an instruction to the agency to establish a list of levels of nutrients in food that, taking into account the makeup of the total daily diet, increase to persons in the general population the risk of diet-related diseases or health-related conditions.

In addition, the agency disagrees with the contention that the definition of "disqualifying nutrient levels" is either overly restrictive or based on an inappropriate scientific basis. The agency stated in the November 1991 proposal that although there are well-established recommendations for dietary intake for fat, saturated fat, cholesterol, and sodium that are consistent with maintaining good health, there are no levels for these nutrients in an individual food generally recognized by the health community to pose an increased risk of disease. However, this statement was intended to point out that scientists have not developed a scheme for transposing quantitative information on the nutrient content of a diet to comparable quantitative information for the broad array of individual foods as they may fit within the context of a healthful diet. Because of this fact, the agency stated in the November 1991 proposal that it did not know of an established or accepted approach for identifying levels for fat, saturated fat, cholesterol, and sodium in an individual food that would increase the risk of a diet-related disease and that would, therefore, disqualify that food from bearing a health claim. In the absence of an established approach, FDA arrived at an approach in which the amounts of fat, saturated fat, cholesterol, and sodium that the agency proposed as disqualifying nutrient levels were the amounts that, in a single food, would make it difficult to construct a diet that meets dietary guidelines, particularly if consumption of the food is encouraged and emphasized by a health claim. Because the guidelines identify dietary levels for specific nutrients (e.g., saturated fat) for which higher levels of intake are linked to an increased risk for a diet-related disease (e.g., heart disease), failure to meet them can reasonably be expected to increase the risk of a disease. Indepth discussions of the agency's conclusions about risk inherently associated with each of the disqualifying nutrients appear elsewhere in this issue of the **Federal Register** in the preambles of the final rules for health claims for dietary lipids and cardiovascular disease, dietary lipids and cancer, and sodium and hypertension.

Accordingly, the definition for disqualifying nutrient levels is fully consistent with the information contained in the legislative history of the 1990 amendments.

2. Disclose rather than disqualify

24. Several comments suggested that Congress sought through the exception process permitted by section 403(r)(3)(A)(ii) of the act to limit the disqualifying effect of nutrient levels to only those nutrients that have a direct effect on the disease that is the subject of the health claim. Some comments suggested that the agency should have utilized the flexibility accorded by Congress to opt for disclosure of nutrients that are not directly related to the disease mentioned in a claim, rather than disqualification of the product from bearing any health claim. In support of their position, the comments cited the discussion on section 403(r)(3)(A)(ii) of the act contained in the House Report on the 1990 amendments (Ref. 1). Comments argued that even though sodium is linked to hypertension, which is a risk factor for heart disease, a product with high sodium content should not be disqualified from bearing a claim about dietary lipids and heart disease because of the lack of major linkage between sodium as a causative factor for heart disease. Another comment, which asserted that prohibiting an osteoporosis claim for whole milk would be misleading because none of the disqualifying levels have any relevance to osteoporosis, also maintained that FDA had made no room for the disclosure permitted by section 403(r)(3)(A)(ii) of the act for a food

containing a nutrient exceeding the disqualifying level.

The agency disagrees with these comments. Section 403(r)(3)(A)(ii) of the act states that a health claim "may only be made if the food for which the claim is made does not contain * * * *any* nutrient in an amount which increases to persons in the general population the risk of *a* disease or health-related condition which is diet related * * *" (emphasis added). That language is clear in that it does not permit a claim for a product containing a nutrient that increases the risk of any diet-related disease or condition and is not limited to a substance that is associated only with the subject disease. The provision then goes on to state that exceptions to this requirement may be made by regulation in the interest of providing consumers with information in maintaining healthy dietary practices. Contrary to the assertion by one comment, FDA provided for the disclosure permitted by section 403(r)(3)(A)(ii) of the act for a food containing a nutrient exceeding the disqualifying level in proposed § 101.14(e)(3).

Because of the time constraints for issuing regulations on health claims, the agency did not exercise the option to develop exceptions to disqualifying nutrient levels. Nevertheless, the changes made in the disqualifying levels that are explained in response to comments 29 and 32 of this document will reduce, but may not eliminate, any need to develop exceptions to disqualifying levels. With those changes, the number of foods that would be disqualified from making a claim will decrease significantly.

Even though § 101.14(e)(3) provides for exceptions from disqualifying levels and the use of an appropriate referral statement, FDA believes that the use of disqualifying levels will be clearer if § 101.14(a)(5) also reflects the fact that exceptions are possible. Thus, FDA has revised this section to state that exceptions to the disqualifying levels may be provided in the specific health claim regulations in part 101, subpart E. The agency will be receptive to petitions that present the reasons that, and the circumstances in which, an exception to disqualification would assist consumers in maintaining a healthy diet.

3. Additional disqualifiers

25. Several comments recommended that health claims be prohibited in labeling for candies, soft drinks, and other sugars-containing foods on the basis of added sugars content. Some comments stated that a Daily Reference Value (DRV) of 50 g for added sugars should be established, and they recommended a disqualifying nutrient level of 8 g of added sugars. This disqualifying level would represent 15 percent of the DRV recommended by the comments. The comments noted that sugars have been associated with the development of plaque, dental caries, and periodontal disease and further noted that the Dietary Guidelines for Americans (Ref. 7) urges the public to consume sugars only in moderation. Another comment asserted that health claims should not be allowed on the label or labeling of a food when more than 15 percent of the food's total calories is contributed by added sugars.

The agency finds that it would not be appropriate to limit health claims on foods on the basis of added sugars either in terms of an absolute amount per serving or as a function of percent of calories per serving. In determining the disqualifying nutrient levels for fat, saturated fat, cholesterol, and sodium, the agency used an approach based on the DRV's for these nutrients. As explained in the proposal to establish DRV's (55 FR 29476), the values for fat, saturated fat, cholesterol, and sodium were based on recommendations that American consumers limit or reduce dietary intake of these nutrients in order to lower their risk of a number of diet-related diseases whose incidence in the general population is considered by the vast majority of public health experts to be unacceptably high. Such recommendations were derived from two publications: The Surgeon General's report (Ref. 5) and the Diet and Health report (Ref. 6) and are reflected in "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 7). One of these recommendations, for example, is for Americans to reduce dietary fat intake from about 37 percent of total energy intake to 30 percent or less. Accordingly, the DRV for total fat is derived from the recommendation that daily total fat intake not to exceed 30 percent of calories. This and other recommendations are believed to have the potential for a substantial reduction in the risk of diet-related chronic diseases in the general population.

Of the comments recommending a DRV of 50 g of added sugars as the basis for a disqualifying level of 8 g, only one provided a rationale for the suggestion. The comment arrived at its recommendation by first estimating in a nonrigorous fashion that the current consumption level is about 100 g per day. The comment then offered that, because FDA concluded in a 1986 report (Ref. 28) that the average American consumes 53 g of added sugars per day, one-half of their 100 g estimate is close to 53 g which should be rounded to 50 g to become the DRV. It offered that, if the agency sets the DRV for added sugars at what the agency considers to be a current consumption level, it would be difficult to argue that the agency has restricted sugars intake too severely.

FDA does not believe that a disqualifying level for sugars can presently be established because of the lack of suitable criteria in the aforementioned comment on which to base a DRV. Even if the comment's estimate of current consumption is scientifically sound, it is significant that no other DRV has been established with average daily consumption as the criterion. Moreover, the public health community has not identified a dietary level above which consumption of sugars has been demonstrated to increase the risk of a disease. Thus, the agency finds that there is no sound basis on which to establish the requested DRV for sugars. Accordingly, the agency is declining to set a disqualifying level for added sugars at this time. Nevertheless, the agency points out that the criteria established in response to comment 87 of this document for limiting health claims based on the nutritional value of a food will provide at least some of the relief requested in that a food fabricated with sugars and few other nutrients will not qualify for a claim.

26. A few comments recommended that FDA prohibit health claims on foods containing any "unnecessary substances," food or color additives or flavor enhancers. One of these comments justified the recommendation by stating that saccharin is associated with a major disease.

FDA does not believe it is appropriate for it to judge whether use of an ingredient is necessary, or to make the mere presence of a food additive disqualify foods from bearing health claims unless the use of the food additive has not been listed by FDA for use in food under section 409 of the act (21 U.S.C. 348). When it passed the Food Additives Amendment in 1958, Congress concluded that use of food additives is in the public interest, provided that their use is safe and not deceptive. For those comments concerned about the safety of food and color additives, the agency advises that the act requires that the use of these additives be shown to be safe before they are listed for use in food. Other ingredients that may be added to food are limited to those that are generally recognized as safe (GRAS) by the scientific community by virtue of their history of use or other scientific knowledge (i.e., GRAS), or whose use

was sanctioned by FDA or USDA before the enactment of the Food Additives Amendment (i.e., prior sanctioned ingredients).

With respect to the comments that specifically mentioned saccharin, FDA did propose on April 15, 1977 (42 FR 19996), to ban its use, based on its interpretation of evidence available from animal studies at that time. However, Congress decided that the additive should be permitted in food and blocked the proposed ban through enactment of the Saccharin Study and Labeling Act. Therefore, unless there is a change in its legal status, the use of saccharin in compliance with § 101.11 (21 CFR 101.11) and § 180.37 (21 CFR 180.37) must be treated the same as any other legally authorized use of an ingredient.

4. Fifteen Percent of the DRV

a. *Criticism of approach.*

27. A number of comments stated that, despite FDA's assertions to the contrary, a total ban on health claims for foods exceeding a disqualifying level would create a good food/bad food image in the minds of consumers. The comments claimed that consumers may turn away from foods that provide significant amounts of essential nutrients simply because the foods do not carry a health claim. One comment noted that whole milk would be prohibited from making a claim about calcium and osteoporosis in spite of the fact that it is recommended as a source of calcium for children 1 to 2 years of age. The comment cautioned that parents may inappropriately substitute skim and low fat milk because of an assumption that whole milk is inferior.

Other comments proposed that if FDA decides to establish disclosure/disqualifying levels for nutrients, the agency should employ extreme care in informing consumers that individual foods do not increase the risk of disease, because it is the total daily diet that must be taken into account.

FDA disagrees with the contention that if foods that exceed a disqualifying level are ineligible to bear a health claim, consumers will perceive those foods as bad. A food without a claim, even if it does not exceed a disqualifying level, may not have the appropriate level of a nutrient to qualify for a claim. For various reasons, a food manufacturer may decide not to label a product with a claim even if the product qualifies. On the other hand, a product bearing a claim is required to provide the consumer with sufficient information to understand how the product may be useful to achieve the claimed effect within the context of the total daily diet. The agency believes that there are sufficient safeguards within section 403(r) of the act that are fully implemented in the final rules on health claims to prevent consumers from being misled about the value of any food based on whether it does or does not bear a health claim.

The agency acknowledges, however, that the full array of all of the new labeling regulations effected by the 1990 amendments may not be immediately understood by consumers. To deal with this, FDA will conduct an education program to effectively communicate how this new food labeling can assist consumers to maintain a healthy diet through informed food selection.

In response to the last group of comments, the agency reiterates that the disqualifying levels represent the amount of these nutrients in a single food that would make difficult the construction of a diet that meets dietary guidelines. They in no way represent a finding by the agency that these levels will cause diet-related disease or that foods that contain nutrients at these levels are unsafe, dangerous, or bad.

28. Other comments contended that an across-the-board disqualifying level based on a set percentage of the DRV for a nutrient could not be justified. One comment stated that it could not support the food composition analysis the agency used in developing the proposed disclosure/disqualifying levels because that approach does not fully meet the requirements of section 403(r)(3)(A)(ii) of the act. Specifically, the comment asserted that FDA's approach to disclosure/disqualifying levels ignores the legal requirement of accounting for the "significance of the food in the total daily diet." The comment claimed that this requirement implies a food consumption analysis that considers how a food is customarily used in the context of a daily diet. Further, the comment said that only a careful examination of food consumption data, in which foods are inherently related to their use in daily diets, can properly address the requirements of the law. The comment offered that the agency's proposed disclosure/disqualifying levels have some basis in daily consumption because of the use of DRV's. However, it said that the evaluation of individual foods in the agency's model is based on food composition values compared to food consumption values derived from DRV's. The comment argued that the composition of a food has no meaning in the context of the daily diet until its customary use is considered. The comment concluded that FDA did not do this, and that this error invalidates the agency's analysis.

The food composition methodology used by the agency in arriving at the proposed disclosure/disqualifier nutrient levels is fully consistent with section 403(r)(3)(A)(ii) of the act. As FDA explained earlier in this preamble in its response to comment 23 of this document, Congress intended that FDA establish these levels by considering the role of the nutrients in food in a way that will enhance the chances of consumers constructing total daily diets that meet dietary guidelines. The focus of this provision was clearly not on consumption of the individual food. Thus, references to "the significance of the food in the total diet" in that section does not imply that a food consumption analysis of how individual foods are used in a daily diet should be made. Instead, that section requires that FDA consider consumption in a far broader context. As explained in the subsequent paragraphs of this response, FDA's approach considers daily food consumption through use of the DRV's.

The DRV's were developed from recommendations in, for example, the Surgeon General's report (Ref. 5) and Dietary Guidelines for Americans (Ref. 7). They reflect current and established scientific evidence related to overall nutrient intake and risk of diet-related diseases. They also reflect total dietary intake from foods in general, but not intake from individual foods. Thus the disclosure/disqualifying nutrient levels are also based on food consumption in general, not just food composition.

Further, in arriving at the numerical value for the disclosure/disqualifying levels, the agency looked at the daily diet as being composed of approximately 20 servings of food and the likely distribution of the subject nutrients in the diet. The agency concluded that such nutrients were likely to be found at significant levels in as many as 10 of those 20 foods. Thus, while the agency did not consider the role of specific individual foods in the diet in arriving at the disclosure/disqualifying levels, the significance of particular types of food, such as those that contain a significant amount of fat, were considered. In sum, FDA's approach considers consumption in a broad manner that enhances the chances of consumers constructing total daily diets that meet dietary guidelines. Accordingly, contrary to the point made in the comment, the agency concludes that it did effectively consider food consumption data in which foods were related to their use in the diet in establishing the disclosure/disqualifying nutrient levels.

b. *Fifteen percent should increase to 20 percent.*

29. A number of comments, mostly from consumer organizations, agreed with the agency's rationale for selecting 15 percent of the DRV as the disclosure/disqualifying level for a specific nutrient; however, many comments from industry objected. In lieu of the 15 percent level chosen by FDA, the latter comments recommended 20 percent of the DRV because that is the amount the agency proposed as a "high" or "major source" nutrient content claim. Other comments strongly urged FDA to raise the disqualifying level to 20 percent of the DRV for cholesterol and sodium.

In addition, comments from industry and a Federal agency expressed concern that the disqualifying levels for fat, saturated fat, cholesterol, and sodium would prevent manufacturers from making potentially beneficial health claims on food that could assist consumers in making dietary changes. Some of the comments claimed that 99 percent of the food items in the categories of poultry, meat, and fish are disqualified from mentioning the health reasons for changes in consumption, despite recommendations from dietary authorities to substitute lean chicken and fish for meat. Similarly, the comments argued that the disqualifying levels would prevent nearly 90 percent of the items in mixed foods (grain), ready-to-eat cereal, and cheese categories and over 80 percent of the items in bread and crackers/salty snacks categories from making health claims. One comment concluded that the disqualifying levels would preclude many foods that could contribute to a better diet from mentioning truthful health reasons for making desirable substitutions, even where there is general scientific agreement on the desirability of these changes.

The agency agrees that the disqualifying levels for fat, saturated fat, cholesterol, and sodium should not serve as impediments to providing consumers with important information on diet and health by precluding health claims for major food groups, such as fish and whole grain cereals, that can be significant foods in a balanced and healthy diet. As FDA explained earlier in this preamble in its response to comment 23 of this document, Congress intended that FDA establish disqualifying levels by considering the role of the nutrients in food in a way that will enhance the chances of consumers constructing total daily diets that meet dietary guidelines. Thus it would not be appropriate for FDA to establish disqualifying nutrient levels that would be so stringent that major food groups that have an appropriate place in a healthful diet would not qualify for health claims.

In concert with the Surgeon General's recommendations, USDA and DHHS provided the American consumer with food guide information on food selection to achieve a healthy diet in the current edition of "Nutrition and Your Health, Dietary Guidelines for Americans" (Ref. 7). Most recently, USDA published "USDA's Food Guide Pyramid" (Ref. 29), which is intended to assist consumers in putting these dietary guidelines into action. The pyramid booklet provides information on dietary moderation, proportionality, and variety to ensure that consumers get the nutrients they need without too many calories or too much fat, saturated fat, cholesterol, sodium, sugar, or alcohol. The pyramid booklet suggests a range of daily servings from five major food groups, one of which includes meat, poultry, fish, dry beans, eggs, and nuts. As the comments indicate, a very large proportion of the items in this food group would exceed one or more of the disqualifying nutrient levels. Consequently, products in this group would not be permitted to bear health claims despite recommendations from dietary authorities to choose, for example, fish, lean meat, and poultry without skin as a way to reduce dietary fat intake. Accordingly, the agency has decided to revise the disqualifying nutrient levels to make it possible for a greater variety of foods in all food groups that are consistent with dietary guidelines to bear health claims.

FDA developed the disclosure/disqualifying levels for fat, saturated fat, cholesterol, and sodium to ensure that health claims are not made for foods that contain a nutrient in an amount that makes it difficult for consumers to comply with dietary guidelines. In developing these levels, FDA found no ready guidance on how to calculate them. The legislative history of section 403(r)(3)(A)(ii) of the act does not suggest what amount of a nutrient in a food should be considered as the limit to ensure compliance with dietary guidelines. Furthermore, current dietary guidance is presented in terms of daily nutrient intake rather than intake from individual foods.

Thus, in the absence of an accepted means for deriving the levels of nutrients in food that could be considered to increase the risk of disease, FDA, after considering the language of the act and its legislative history and based on the agency's scientific expertise, arrived at a tentative approach that was based on the proposed DRV's and available information on food composition and dietary intake patterns. The agency considered that a consumption pattern of individual foods that allowed for the intake of 100 percent of the DRV's would not increase the risk of diet-related disease, but that intakes resulting in the consumption of 200 percent of the DRV would do so. Therefore, an amount of a nutrient that would not increase the risk of disease would fall somewhere between 100 percent and 200 percent of the DRV. Based on the assumptions that diets generally include approximately 20 food/beverage items per day (Refs. 8 through 10), and that, given the uneven distribution of nutrients among the food categories, only about half of the foods consumed during a day will contain the nutrients of concern, the agency tentatively concluded that an increase in risk from an individual food was likely to result if it contained between 10 and 20 percent of the DRV per serving of fat, saturated fat, cholesterol, or sodium.

Based on food composition data available to the agency, FDA evaluated the kinds and types of foods that would be disqualified from bearing a health claim on the 10, 15, and 20 percent levels. Based on this evaluation, FDA tentatively concluded that 15 percent of the DRV represented the amount of the nutrients in question that increases to persons in the general population the risk of a diet-related disease or health-related condition.

After reviewing additional information on food composition (Ref. 30) and the comments recommending that the disclosure/disqualifying levels be raised from 15 to 20 percent of the DRV's, FDA is persuaded that its approach to calculating this level should be modified. FDA acknowledges that its primary concern in its initial development of these criteria was that foods that contain levels of nutrients that are not consistent with dietary recommendations be precluded from making a health claim. However, comments on this approach strongly urged that FDA also ensure that types of foods that are consistent with dietary recommendations—or, more specifically, types of foods whose increased consumption has been promoted in dietary recommendations—be able to bear claims if they meet the specified definition for the claim. In other words, comments argued that the disclosure/disqualifying levels should be sufficiently liberal so as to maximize the number of foods that bear claims and to allow claims on foods that are generally regarded as desirable components of an overall healthy diet,

assuming that the food meets the basic definition for the claim.

Based on consideration of foods highlighted by the comments as well as on a review of the food composition data available to the agency, FDA agrees that the use of a 20 percent DRV criterion will permit foods that are appropriately included in an overall healthy diet, for example a greater variety of bran and oat breakfast cereals or legume and vegetable products, to bear a health claim, even though they would not have been permitted to do so under the 15 percent DRV criterion. Furthermore, FDA finds compelling the argument made in comments that the criterion for "high" levels of a nutrient in a food can be applied not only as proposed (i.e., to emphasize the presence of a nutrient when it is considered desirable) but also can provide a consistent and appropriate basis for defining the levels at which the presence of a nutrient may be undesirable.

FDA acknowledges the debate on the issue that an exact level is not readily identifiable for a nutrient in a food that increases the risk of a disease or health-related condition to persons in the general population. With levels set at 20 percent of the DRV's for fat, saturated fat, cholesterol, and sodium, the question arises as to whether there are foods included among those containing 20 percent or less of a DRV that may lead to a diet inconsistent with dietary guidelines for maintaining good health. On reconsideration, the agency believes that the answer is no. Since the primary consideration from dietary guidance for avoidance of disease risk focuses on nutrient composition of the diet, and since there is no generally accepted way to extend that risk to the multiplicity of foods that may be selected in a daily diet while remaining consistent with dietary guidance, the agency finds that, taking into account the significance of the foods in question (that is, foods with 20 percent or less of the DRV for fat, saturated fat, cholesterol, or sodium) in the total daily diet, it is appropriate to adjust the disqualifying levels to the higher value of 20 percent of a DRV. In doing so, the agency is balancing the availability of valid information against the probability that food with that information will result in diets that increase the risk of a disease or health-related condition. FDA believes that, in the 15 to 20 percent range for establishing disqualifying levels, the importance of providing health claim information is greater than the possibility that risk of disease will be increased. Above 20 percent, however, the agency believes that that risk will increase and thus section 403(r)(A)(ii) of the act should be brought to bear. Therefore, FDA finds that, if a food contains more than 20 percent of the DRV for fat, saturated fat, cholesterol, or sodium (i.e., more than 13 g of fat, 4 g of saturated fat, 60 mg of cholesterol, or 480 mg of sodium) per reference amount customarily consumed or per label serving size it may not bear a health claim because these levels in an individual food can lead to a diet inconsistent with dietary guidelines for maintaining good health. Moreover, as explained in the response to comment 32 of this document, if a food that has a reference amount of 30 g or less or of 2 tablespoons or less contains more than 20 percent of the DRV for any of these nutrients per 50 g of food, it may not bear a health claim because claims on such nutrient-dense foods would be inconsistent with dietary guidelines.

c. *Increase for meals and meal replacements.*

30. Some comments suggested that FDA establish separate disqualifying levels for meal-type products at 25 percent of the DRV. They contended that products ordinarily consumed as meals contribute much more to the total diet than do individual foods. The comments argued that the single-food disqualifying levels for these meal-type items is too strict. A disqualifying level of 25 percent DRV for saturated fat, total fat, sodium, and cholesterol would ensure that persons eating three meals a day plus a snack would not exceed 100 percent DRV of any nutrients of concern.

The agency agrees that single food disqualifying levels are too strict when applied to meal-type products, which contain multiple servings of food. Because disqualifying levels for health claims are the same as disclosure levels for nutrient content claims, and because both are derived from the same statutory standard regarding nutrient levels in amounts that increase the risk of a diet-related disease in the general population, the definition for disqualifying levels in new § 101.14(a)(5) has been revised to be consistent with comparable requirements in new § 101.13 on disclosure levels for nutrient content claims for meal-type products published elsewhere in this issue of the Federal Register.

FDA is now providing for the definition of "meal product" in new § 101.13(l) and "main dish product" in new § 101.13(m) within the context of providing for nutrient content claims. As described in the nutrient content claims final rule, the agency is adopting different criteria for nutrient content claims for these products as compared with individual foods. The definition for a "meal product," which is described in more detail in the nutrient content claims final rule, is that: (1) It is represented as, or commonly understood to be, a dinner, lunch, breakfast, or other meal; and (2) it makes a major contribution to the diet by weighing at least 10 ounces (per labeled serving), containing at least 3 different foods from at least 2 of 4 food groups, and containing not less than 40 g of each of the 3 different foods. The definition for a "main dish product" is that: (1) It is represented as or is in a form commonly understood to be a main dish, and (2) it weighs at least 6 ounces per labeled serving, contains at least 2 different foods from 2 of 4 food groups, and contains not less than 40 g of a food from each of 2 food groups.

FDA has considered the appropriate disclosure/disqualifying level for main dish and meal products. As mentioned above, comments have suggested that the criterion be based on the amount per 100 g of product. Using this approach, the amounts used for individual foods (i.e., 13 g of total fat, 4 g of saturated fat, 60 mg cholesterol, and 480 mg sodium) would be the amount per 100 g of a meal or a main dish. FDA however notes that, on this basis, a meal weighing 10 ounces (280 g) would be subject to disclosure/disqualification if it contained approximately 36 g of fat or 55 percent of the DRV. A single meal product weighing 12 ounces (336 g)—not an uncommon weight for a meal—would be subject to disclosure/disqualification if it contained approximately 44 g of fat or about 67 percent of the DRV for total fat. If it is assumed that a "meal" constitutes one-fourth of a total day's nutrient/calorie intake, which, if anything understates the contribution of a meal, this criterion is seen to be too high because a meal could contribute more than half of the total amount of one of the nutrients in question (i.e., fat, saturated fat, cholesterol, or sodium) generally recommended as a total daily intake and yet still bear a health claim.

The comments received offered no approaches other than use of the "per 100 g" basis relative to disclosure/disqualifying levels for main dishes and meals. FDA, therefore, has developed an approach that extends the rationale used for individual foods to main dishes and meals. Specifically, given that main dishes and meals constitute a larger portion of the diet than individual foods, the criterion for disclosure/disqualification for main dishes and meals should be a greater percentage of the DRV than for individual foods.

FDA has determined that criteria of 30 percent of the DRV as a disclosure/disqualifying level for main dishes and of 40 percent of the DRV as that level for meals are appropriate. Assuming a typical consumption of three meals and a snack, each of which contain 40 percent of the DRV for a particular disclosure/disqualifying nutrient, and foods that sometimes accompany meals such as beverages, bread, and desserts that contribute an additional 40 percent of the DRV for the nutrient, 200 percent of the DRV would be consumed during the day. As discussed in the response to comment 29 of this document, FDA has concluded that on balance, given the benefits and the probabilities that risk of disease will be increased, a disqualifying level based on a total dietary intake of 200 percent of the DRV is appropriate.

Disclosure/disqualifying levels for main dishes are appropriately placed at 30 percent because it is likely that consumption levels of these products is between the level for individual foods and the level for meals. Therefore, FDA has set the criterion at 30 percent which is between the 20 percent criterion for individual foods and the 40 percent criterion for meals. Finally, FDA's review of available data suggests that these criteria have practical application in that the criteria of 30 and of 40 percent of the DRV would not be overly restrictive (Ref. 35). Accordingly, the definition of disqualifying nutrient levels in new § 101.14(a)(5) has been revised to incorporate these changes for meals and main dish products.

31. One comment from a manufacturer of foods for special dietary uses suggested that the proposed disqualifying provisions of proposed § 101.14(a)(5) should not apply to a formulated product presented as a meal replacement where a serving provides one-fourth to one-third of the daily nutrient intake based on calories. Rather, the comment suggested that the disqualifying levels should be based on the amount of total fat, saturated fat, cholesterol, or sodium when the amount of any of these substances exceeds the equivalent portion of the DRV on a caloric basis. For example, according to the comment, a meal replacement that provides 25 percent of the daily caloric intake in a single serving should have the disqualifying levels set at or above 25 percent of the DRV's. The comment said that such a provision would provide a standard for these products consistent with the regulation. Each "serving" of the formulated product would represent an entire meal and would replace several servings of conventional food. Establishing disqualifying levels on this basis, the comment said, would allow consumers access to important health information. The comment suggested that the proposed regulation be modified to read as follows:

> Formulated meal replacement products that provide 25% to 33-1/3% of the daily caloric intake shall be disqualified when the level of fat, saturated fat, cholesterol, or sodium exceeds, on a caloric basis, the equivalent portion of the Daily Reference Value [21 CFR 101.9(c)(12)(i)].

The agency acknowledges the point made by this comment that a meal replacement product, particularly one that is a food for special dietary use, may be sufficiently different from a serving or amount of a conventional food to warrant a different criterion for disqualifying nutrient levels. Nevertheless, the agency does not believe that it is appropriate to modify the codified language as recommended because of a lack of essential information needed to implement the change. Specifically, where the proposed codified language applies to "formulated meal replacement products," there is no definition or other characterizing information that identifies this class of products.

The agency published proposed regulations on June 14, 1974, to establish a nutritional quality guideline and a common or usual name for formulated meal replacements (39 FR 20905). Subsequently, however, those proposals were withdrawn. Although they may serve as a basis to reconsider what had been proposed, a significant number of changes have occurred in the intervening 18 years with regard to the regulations and policy on the nutrient content of foods.

For example, the proposed nutrition quality guideline regulation defined a formulated meal replacement, in part, as a product that supplies a minimum of 700 kilocalories per serving (the term "calorie" has the same meaning as "kilocalorie" in the text that follows), unless the product is represented for use in a reduced calorie diet (39 FR 20905, June 14, 1974). On the presumption that a meal should provide at least 25 percent of daily caloric intake, the value of 700 calories per serving was derived from a proposed intake standard of 2,800 calories per day. Subsequently, as reflected in the current fortification policy (21 CFR 104.20), the energy intake standard has been lowered to 2,000 calories per day. This value is the same as the reference caloric intake that FDA used in determining the DRV's, published elsewhere in this issue of the **Federal Register**. Accordingly, the agency advises that with the necessary steps to establish a definition and nutrient composition and nutrition quality requirements for the class of "meal replacement products," particularly those that are foods for special dietary use, consideration may be given to providing an exception to disqualifying levels for that class of products.

The agency has examined several products currently in the marketplace promoted for use, among other things, as either a "meal replacement" or as a "balanced meal" that included a formulated ready-to-consume fluid product and dry mixes for addition to fluid milk to produce an "instant breakfast drink." The former, but not the latter, type product bore other labeling for use of the product to either lose or gain weight, thus classifying the product as a food for special dietary use. A single serving of the ready-to-consume product provides 360 calories, whereas the dry mixes provide 220 calories when combined with 8 fluid ounces of skim milk. From nutrition labeling information, neither type of product exceeds the disqualifying levels for fat and sodium defined in new § 101.14(a)(5) for an individual food. From the list of ingredients and nutrient content information from standard data bases, it is also unlikely that either product would exceed the disqualifying levels for saturated fat or cholesterol. Further, it appears that if a serving of the ready-to-consume meal replacement were adjusted to increase the caloric yield from 360 to 470 calories per serving, the disqualifying levels for fat, saturated fat, cholesterol, and sodium would still most likely not be exceeded. Although this assessment, admittedly, is extremely limited in scope, the agency concludes that the disqualifying levels in new § 101.14(a)(5) for an individual food will apply to a product promoted as a meal replacement until a more appropriate requirement is established by regulation.

d. *Per 100 grams.*

32. A number of comments from industry and from other Government agencies objected to the part of the proposed definition for "disqualifying nutrient levels" in proposed § 101.14(a)(5) that tied such levels to the amount of fat, saturated fat, cholesterol, or sodium "per 100 g." One comment asserted that 100 g means nothing to the public and suggested that standardized serving sizes should be the basis of labeling. Others agreed that the "per 100 g" criterion is unnecessary with the adoption of standardized serving sizes, which, the comments asserted, effectively eliminate the agency's concern that manufacturers may

manipulate serving sizes to make their products appear more attractive. One comment cautioned that using both the 100 g and serving size requirements risks substantial confusion.

FDA does not agree that a weight-based criterion is unnecessary. The agency notes that section 403(r)(3)(B)(iii) of the act states that a claim should enable the public to comprehend the information in a claim and understand the relative significance of that information in the context of a total daily diet. Because certain foods are consumed in small amounts and thus have small serving sizes, it is possible that a food dense in a nutrient such as fat or sodium could qualify for a health claim because the serving size of the food is so small that there is not a sufficient amount of the nutrient present to disqualify the food. Accordingly, the nutrient density, or weight-based, criterion was developed to deal with foods with small serving sizes that may be consumed more frequently than once a day.

However, the food itself could be inconsistent with dietary guidelines in that it has been identified as a food to be limited in the diet. "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 7) states that certain types of foods high in fat, for instance, should be limited in the diet without regard to the amounts typically consumed in a single serving. Furthermore, the recommendations provided in "USDA's Food Guide Pyramid" (Ref. 29) are consistent with the guidance to limit the intake of certain types of foods regardless of serving size. Claims on such foods would promote their consumption and, thus, fail to set the food in its proper dietary context.

Therefore, FDA has concluded that criteria for health claims based solely on serving size would be inconsistent with dietary guidance and would fail to respond to section 403(r)(3)(B)(iii) of the act, which requires that the claim set the food properly in the context of the diet. This conclusion is supported by the comments to the docket discussed in the response to comment 87 of this document, which stated that health claims should be prohibited on foods that are inconsistent with a sound dietary pattern. Moreover, claims intended to promote the consumption of a food that appear on a food that is inconsistent with dietary guidelines could be misleading to consumers under section 403(a) of the act and, thus, such claims are inappropriate.

However, the agency has concluded that the weight-based criterion is only needed for foods with small serving sizes that include those foods with reference amounts of 30 g or less or 2 tablespoons or less. For foods with reference amounts above 30 g or 2 tablespoons, the per label serving size or per reference amount customarily consumed criteria are sufficient to prevent nutrient-dense foods from bearing health claims.

Accordingly, FDA has provided for a weight-based criterion in addition to the criterion that specifies the amount of nutrient present per reference amount customarily consumed and per label serving. The weight-based criterion precludes claims on nutrient-dense foods and would qualify for a health claim solely because they have very small serving sizes.

A weight-based criterion for foods with small serving sizes is also used with nutrient content claims, which are discussed in a final rule published elsewhere in this issue of the **Federal Register.** As discussed in that document, comments to the nutrient content claims proposal stated that basing the criterion on per 100 g may be overly restrictive. These comments pointed out that the per 100-g criterion precludes claims on foods that are consistent with dietary guidelines, such as whole grains and cereals. Alternative and less restrictive criteria were suggested including a criterion based on 50 g rather than 100 g. As discussed in the nutrient content claims final rule, FDA has been persuaded that it is appropriate to use 50 g rather than 100 g as the weight-based criterion.

To ensure that its treatment of disqualifier and disclosure levels is consistent, FDA has reexamined the 100-g criterion for use with health claims. Data analyses (Ref. 31) demonstrate that changing from 100 g to 50 g and applying the criterion only to foods with small serving sizes allows a number of foods that would otherwise have been precluded from bearing a claim and that are consistent with dietary recommendations, such as certain cereals and whole grains as well as fish and milk products, to qualify for health claims. Moreover, such a change would allow only a few foods that are inconsistent with dietary guidelines to bear claims. Therefore, to provide for claims that are consistent with dietary guidance, FDA is providing for a weight-based criterion for foods with small serving sizes based on per 50 g rather than per 100 g. In addition, for dehydrated foods that must have water added to them prior to typical consumption, the per 50-g criterion refers to the "as prepared" (that is, hydrated) form.

The agency also disagrees that using three criteria, nutrient density, reference amount customarily consumed, and label serving size, to determine disqualifying levels runs the risk of confusing consumers. The determination as to whether a food contains a disqualifying level of a nutrient is not discussed on the label or in labeling. Thus, there is no basis on which a consumer could be confused.

e. *Relevant nutrients.*

i. *Fat and saturated fat.*

33. One comment recommended that in conjunction with the health claim on skim milk and 1 percent lowfat milk, the agency requires that the products display a statement that "whole milk is more appropriate for the growth and development of children under two years who are drinking milk." The comment noted that children in this age group require an adequate amount of fat in their diet for proper growth and development.

FDA does not believe that skim and lowfat milk should be required to bear the suggested statement. The health claim about calcium and osteoporosis is directed primarily to those individuals with known family histories of osteoporosis and to adolescent and young adult Caucasian and Asian American women. Such claims are not directed to children. In fact, health claims are prohibited, except in very limited circumstances, wherever a food is represented or purports to be for infants and toddlers less than 2 years of age. Therefore, FDA rejects the request in this comment.

34. Some comments asserted that the disqualifying levels for fat and saturated fat were too high and should be lowered.

The agency disagrees with this contention. Absent a showing to the contrary, and the comments did not contain such a showing, the agency has no basis to find that levels in a food of fat and saturated fat of less than 15 percent of the respective DRV's increase the risk of a diet-related disease. Further, as explained above, FDA has reassessed the issue and concluded that the disqualifying levels for fat and saturated fat should be raised to 20 percent of their DRV's. The agency finds that this decision is consistent with dietary recommendations to limit energy intake from fat and saturated fat to 30 and 10 percent of calories, respectively. Accordingly, the agency rejects the comment's recommendation.

35. One comment stated that the disqualifying regulations for fats and saturated fats should be adjusted to reflect the use of reduced calorie novel fats and fat replacers. The comment

explained that products employing novel fats should be eligible to display a lipid and cardiovascular health claim consistent with other requirements for this claim. The comment asserted that the identity of fat should be limited to those materials that do in fact provide measurable bioavailable fatty acids and calories. The comment asserted that fatty acid containing fat substitutes that are essentially nondigestible do not qualify as fats and should be treated separately. The comment stated that the quantity of fat should be determined by the amount of bioavailable fatty acids that such a fat substitute contains. This approach, the comment said, would provide a common basis for quantifying the fat equivalence of novel fats as well as mono- and diglycerides, phospholipids, and "natural" fats of limited digestibility. Under it, total fat could be quantified, and fatty acid type could be expressed as the triglyceride equivalent of the bioavailable fatty acid fraction. For the novel fats, the average characterizing bioavailability could be established by the manufacturer and submitted to FDA as part of a petition for regulatory food-use approval. Application of a "bioavailability" index for fats would be similar to the use of the Protein Digestibility Corrected Amino Acid Score or Protein Efficiency Ratio used to characterize proteins and of the bioequivalence values assigned to vitamin products.

The agency does not disagree with the comment's main point that the quantity of fat in a product, which determines whether a claim can be made, should be determined by the amount of bioavailable fatty acids that the product contains. Total fat content is a part of nutrition information mandated by section 403(q)(1)(D) of the act. Thus, any claim (i.e., a health claim or nutrient content claim) based on fat content must be based on the amount of fat declared in the nutrition label. How total fat content is determined is addressed in the regulation on mandatory nutrition labeling, new § 101.9, published elsewhere in this issue of the **Federal Register**. Thus, the agency sees no need to provide for a separate method in the health claims regulation for purposes of declaring whether a food contains a disqualifying, or a qualifying, level of fat.

The agency advises that any proposal to modify the methods for determining the total fat and fatty acid content of a food may be submitted as a petition to amend new § 101.9. Moreover, as explained in the final rule on mandatory nutrition labeling, when seeking approval from the agency for use of a fat replacer or novel fat in food, the petitioner should include information on the caloric value and macronutrient content of the ingredient. Nutrient content requirements for health claims will be subject to the appropriate requirements for nutrition labeling and any other related regulation.

ii. *Cholesterol.*

36. Many comments expressed support for the proposed cholesterol disqualifying levels. One Federal agency objected to the proposed cholesterol disqualifying level which, it contended, appears to be based on behavioral assumptions about consumption patterns that are not borne out by USDA data. Another comment urged that FDA raise the disqualifying level for cholesterol to one-third of the DRV.

As discussed in detail above, FDA has reassessed the disqualifying levels for cholesterol, fat, saturated fat, and sodium. The agency has concluded that the levels for all 4 can be set at 20 percent of the DRV's. Accordingly, having concluded, for the reasons set out previously, that a nutrient level in excess of 20 percent of the DRV for each of the 4 disqualifying nutrients is associated with an increased risk of a diet-related disease or health-related condition, the agency rejects the recommendation that the disqualifying level for cholesterol be raised to one-third of the DRV.

iii. *Sodium.*

37. Some comments challenged FDA's decision to set a disqualifying level for sodium. One of these comments noted that it was FDA and not Congress that identified sodium as a nutrient of concern because sodium, like fat, saturated fat, and cholesterol, has been "associated with increased risk of disease." Several comments asserted that there is a lack of significant scientific agreement on a link between dietary sodium and hypertension.

One comment cited reports by the Surgeon General and others as proof of the divided and inconclusive opinions of experts in the field. Furthermore, the comment charged that FDA had failed to independently analyze the results of the INTERSALT study, which, the comment alleged, refutes the traditional sodium-hypertension hypothesis.

Another comment submitted published studies that it claimed supported the comment's position that there is no rational basis for concluding that any single food contains sodium "in an amount which increases to persons in the general population the risk of a disease or health-related condition which is diet related," and that "FDA has absolutely no statutory or scientific basis by which to establish any disqualifying level for sodium." One comment warned that a final decision by FDA to set such a level without proper regard to conflicting scientific data would not meet the statutory requirements of sections 403(r)(3)(A)(ii) or 403(r)(2)(B)(ii) of the act governing the establishment of disqualifying and disclosure nutrient levels and would clearly constitute arbitrary and capricious rulemaking.

The agency disagrees with the contention that sodium has not been associated with increased risk of disease. As explained in detail in the specific health claim document on this subject that is published elsewhere in this issue of the **Federal Register**, the available data, including the INTERSALT study, establish that dietary sodium intake is associated with hypertension. This discussion is referenced. For example, "Dietary Guidelines for Americans" (Ref. 7) states:

> Many American diets have too many calories and too much fat (especially saturated fat), cholesterol, and sodium. * * * Such diets are one cause of America's high rates of obesity and certain diseases—heart disease, high blood pressure, stroke, diabetes, and some forms of cancer.

FDA is convinced not only of the scientific soundness of the sodium/hypertension health claim but also of the appropriateness of a disqualifying level for sodium.

38. One comment suggested that it would be appropriate to include on the label of a food, in immediate proximity to any health claim, information on the sodium content (such as that required by new § 101.13(h) published elsewhere in this issue of the **Federal Register**), thus benefitting the small segment of the population for which sodium may be of concern, while providing a health message that could potentially benefit a much larger population.

FDA recognizes that there may be a number of different ways to display selected information, like sodium content, to meet various consumer needs or preferences. Although a display of sodium content information like that recommended by the comment may benefit a certain segment of the population, the 1990 amendments do not provide the agency with authority to require for health claims the type of nutrient disclosure required for nutrient content claims by new § 101.13(h). That regulation derives from section 403(r)(2)(B)(ii) of the act which states that if a food that bears a nutrient content claim that increases to persons in the general population the risk of a disease or health-related condition, the claim shall also identify such nutrient. Under those same circumstances,

however, the 1990 amendments do not permit a health claim to be made. The regime by which nutrient content claims are made is different than that for health claims.

The agency points out, nevertheless, that any food with a health claim will also bear nutrition information listing sodium and other nutrient content. Although the information on sodium content may not be displayed as conveniently or prominently as that recommended by the comment, it will, nevertheless, be readily accessible on a product's label.

39. Other comments called for a higher disqualifying level for sodium. One comment argued that the decision to set the sodium disqualifying level at 15 percent of the DRV is not as solidly based as the disqualifying levels for fat, saturated fat, and cholesterol. The comment further concluded that because much of the sodium in the American diet is concentrated in a few products, a product containing 20 percent of the DRV for sodium (480 mg) could easily be incorporated into a diet without increasing the risk of hypertension. Another comment agreed that the proposed sodium disqualification levels are too strict and noted that many breads would be restricted from making any health claims if the proposed level is adopted.

Another comment urged that FDA raise the disqualifying level for sodium to one-third of the DRV. The comment warned that setting such a low disqualifying level as 15 percent of the DRV for sodium would discourage manufacturers from producing lowfat products, because salt is required to improve the taste, and thus the marketability, of many such lowfat products.

As discussed previously in this section, FDA has reassessed its analysis for defining disqualifying levels and determined that the levels can be set for sodium and the 3 dietary lipids at 20 percent of the DRV's. Having concluded that nutrient levels greater than 20 percent of the DRV's, including that for sodium, increase the risk of diseases or health-related conditions that are diet related, FDA rejects the recommendation that the disqualifying level for sodium be set at one-third of that nutrient's DRV.

f. *Exception from disqualification.*

40. Some comments stated that exceptions to the disqualifying levels should not be granted. Other comments urged FDA to consider requests for exemptions from the disqualifying levels only on a case-by-case basis, and only when virtually all foods containing significant levels of the nutrient would otherwise be disqualified. One of these comments asserted that none of the currently proposed health claims would warrant an exception. Furthermore, many of the comments suggested that if FDA did grant an exception, a statement disclosing the level of the disqualifying nutrient should appear prominently next to the health claim.

The agency disagrees with those comments recommending that exceptions to the disqualifying levels should not be granted. Similarly, it is not convinced that the only basis to permit exceptions is when virtually all foods containing significant levels of the health claim nutrient would be disqualified. Section 403(r)(3)(A)(ii) of the act provides the Secretary (and FDA, by delegation) discretionary authority to permit a claim for a food that would otherwise be disqualified if the Secretary determines that the claim would assist consumers in maintaining healthy dietary practices. The agency is prepared to consider whatever arguments may be brought to bear with respect to a particular claim or with respect to a particular nutrient as to why an exception to a disqualifying level should be granted. Thus, the agency is not prepared to limit its discretion in the manner suggested by several of the comments.

If an exception to the disqualifying levels is authorized, section 403(r)(3)(A)(ii) of the act specifies that the label of the product contain a disclosure of the type required by section 403(r)(2)(B)(ii) of the act. Thus, the disclosure will have to be made prominently and in immediate proximity to the claim. It will have to identify the nutrient, and it will have to refer the consumer to the labeling panel where nutrition information may be found.

41. Other comments urged the use of discretion in permitting health claims for foods in cases where such claims would assist consumers in maintaining healthy dietary practices. Oils and margarine were cited as examples of foods for which exceptions should be made to provide consumers with information on the health reasons for choosing oils that are lower in saturated fat, because all oils exceed the disqualifying level of 11.5 g of fat. One comment emphasized the importance of focusing on the type of fat in the fats that are consumed and concluded its comment by suggesting that FDA could address its concern about total fat by requiring a clear message on such products that consumers should consume less fat.

The agency intends to use discretion in permitting health claims that encourage certain dietary practices generally recognized by the public health community as being consistent with guidelines for maintaining and promoting good health. FDA acknowledges that "Dietary Guidelines for Americans" (Ref. 7), while recommending that diets low in fat be chosen, also provides advice on how certain fats and oils used sparingly can assist the consumer in maintaining a relatively low saturated fat intake. Although fats and oils obviously exceed the disqualifying level for fat, section 403(r)(3)(A)(ii) of the act does permit exceptions, as discussed previously. Accordingly, FDA is willing to consider a petition that provides a basis for excepting certain fats and oils based on compositional or other characteristics from being disqualified from bearing a particular health claim.

42. A number of comments asked that FDA exempt milk and other dairy products from the disqualifying levels for fat and saturated fat. One comment noted that dairy products contribute 76.8 percent of the dietary calcium in the food supply, yet contribute only 20 percent of the saturated fats and 12 percent of the total fat. The comment contended that allowing only fat-reduced dairy products to make a calcium/osteoporosis claim would be misleading to those individuals who prefer whole milk to reduced-fat milk.

While milk and other dairy products do in fact contribute a large percentage of the daily supply of calcium, the agency noted in the preamble to the proposed regulations that lowfat and skim milk will be able to bear a health claim under proposed § 101.14(a)(5), as will many products made from these reduced-fat milks. FDA, therefore, cannot conclude that an exception for whole milk and other dairy products that exceed the fat disqualifying level would assist consumers in maintaining healthy dietary practices.

III. Preliminary Requirements for a Claim

FDA proposed several criteria in proposed § 101.14(b) that would have to be met before a substance would qualify to be the subject of a health claim. These criteria reflect not only the requirements of section 403(r) of the act but also the fact that FDA is charged with ensuring that the food supply is safe, and that the food label is not misleading. Given that agency evaluations of the validity of a health claim will be resource intensive, FDA proposed not to make such an evaluation unless a petition for a health claim demonstrates that the preliminary requirements are met.

A. Effect on General Population

As proposed, § 101.14(b)(1) stated:

> The substance must be associated with a disease or health-related condition for which the general U.S. population, or an identified U.S. population subgroup (e.g., the elderly) is at risk, or, alternatively, the petition submitted by the proponent of the claim otherwise explains the prevalence of the disease or health related-condition in the U.S. population and the relevance of the claim in the context of the total daily diet and satisfies the other requirements of this section.

43. Several comments endorsed, or advised that there was no objection to, the agency's preliminary requirement in proposed § 101.14(b)(1). Some of these comments stressed that the agency should always interpret this provision with flexibility. One comment asked for clarification as to whether a proven substance-disease claim would be allowed if the affected population was few in number or not readily identifiable as a subpopulation (e.g., vitamin D insufficiency in an undefined population group).

FDA intends to apply a flexible approach in interpreting this provision. The proposed alternative aspect of the provision, which would permit petitioners to explain the prevalence of the disease or health-related condition in the U.S. population and the relevance of the claim in the context of the total daily diet, evidences a determination by FDA to disqualify as few proposed claims as possible under this provision. However, if a proposed claim is ultimately authorized by FDA that involves an affected population that is few in number, that fact will have to be declared in the labeling in conjunction with the claim. Where the affected population is not readily identifiable, information about the prevalence of the disease or health-related condition in the U.S. population will be a material fact and thus will have to be provided in conjunction with the claim if the claim is not to misbrand the product.

As explained previously in this preamble (see comment 2 of this document), FDA does not believe that the 1990 amendments pertain to claims about diseases resulting solely from classical deficiencies of vitamins and essential minerals. Thus, for example, a claim about the benefits of vitamin D in reducing the risk of rickets, if not representing the product as a drug, needs no preclearance under the provisions of new § 101.14. However, such claims must be truthful and not misleading. In view of the fact that very few people are at risk of vitamin D deficiency disorders, a claim about the benefits of vitamin D in preventing vitamin D insufficiency would be misleading where the claim does not explain that few individuals in the United States are at risk of such insufficiency. Further, the claim would need to be more specific about the affected population to be adequately informative. For example, the claim might advise that although the vast majority of the U.S. population is not at risk for vitamin D deficiency disorders, the vitamin may be effective in reducing the risk of vitamin D deficiency problems in some segments of the elderly who are house-bound for prolonged periods and are not exposed to sunlight.

B. Components of Food within the Context of a Daily Diet

New § 101.14(b)(2) and (b)(3)(i) contain provisions requiring that the substance be a component of food. If the substance is present at decreased dietary levels, under new § 101.14(b)(2), it must be a nutrient that is required to be included in nutrition labeling (e.g., cholesterol, total fat). If the substance is present at other than decreased dietary levels, under new § 101.14(b)(3)(i), it must contribute taste, aroma, or nutritive value, or any technical effect listed in § 170.3(o) to the food, and must retain that attribute when consumed at levels that are necessary to justify a claim.

1. General

44. One comment suggested that FDA predetermine for each nutrient appearing in an approved health claim a level below which the nutrient is considered to be present in the context of the total daily diet and above which the nutrient is considered to be present at therapeutic levels.

FDA does not believe that it is practicable or appropriate for the agency to attempt to identify any single nutrient level as a boundary between those levels that are within the context of the daily diet and those which are therapeutic. The agency simply does not have sufficient resources to devote to the suggested determinations without unduely sacrificing resources from other high priority regulatory matters. Instead, FDA believes that it is more appropriate that the burden be upon the petitioner to demonstrate that the claimed effect actually can be achieved through consumption of dietary levels of the substance. At such levels, the presence of therapeutic effects should not be at issue.

2. Section 101.14(b)(3)(i)

45. Some comments stated that the eligibility restrictions on the term "substance" in proposed § 101.14(b)(3)(i) are too restrictive and asked that they be removed. One comment asserted that the agency is creating needless procedural confusion by having a broad definition of the term "substance" in proposed § 101.14(a)(2), which it then immediately narrows in proposed § 101.14(b)(3)(i). A few comments contended that, if FDA retains the food eligibility restrictions in the final rule, the agency should permit a broader interpretation of what constitutes food. Another comment stated that although the phrase "taste, aroma, or nutritive value" is borrowed from the Seventh Circuit's opinion in *Nutrilab Inc.* v. *Schweiker*, 713 F.2d 335, 338 (7th Cir. 1983), the court noted in that decision that these food characteristics were only the primary reasons why people consume food. The court, according to the comment, did not intend to give an all-inclusive list. One comment stated that not all of the other possible food characteristics are encompassed in the listing provided in § 170.3(o). Some comments asserted that food should include everything that can be consumed.

FDA does not believe that it is overly restrictive to require, as it does in proposed § 101.14(b)(3)(i), that a substance be a food or a component of food for it to be the subject of a health claim. Section 403(r) of the act describes the circumstances in which a food will, and will not be, misbranded if it bears a health claim. Thus, it is appropriate for the agency to make it incumbent upon the proponent of a health claim to demonstrate that the substance that is the subject of the claim is a food or component of food.

FDA believes that the framework that it has created in its regulations is appropriate and fully consistent with the act. Under it, manufacturers will be able to make claims that characterize the relationship between any substance and a disease or health-related condition so long as the substance achieves its effect through its use as a food, that is, through its nutritional value.

FDA disagrees with the comments' interpretation of the *Nutrilab* decision and believes that the agency's reliance on the case is justified. The *Nutrilab* court adopted a "common sense" definition under section 201(f)(1) of the act: "When the statute defines 'food' as 'articles used for food,' it means that the statutory definition of 'food' includes articles used by people in the ordinary way most people use food—primarily for taste, aroma, or nutritive value." *Nutrilab*, 713 F.2d at 338. Other courts have followed suit. (See *United States* v. *Undetermined Quantities of Cal-Ban*

3000, 776 F. Supp. 249, 254–55 (E.D.N.C. 1991); *American Health Products Co.* v. *Hayes*, 574 F. Supp. 1498, 1508–09 (S.D.N.Y. 1983), aff'd, 744 F.2d 912 (2d Cir. 1984).) By describing taste, aroma, and nutritive value as the "primary" reasons for consuming food, the *Nutrilab* court acknowledged that a food consumed for one of these reasons might sometimes also be consumed for an additional purpose. 713 F.2d at 338 (giving prune juice and coffee as examples of foods that "may be consumed on occasion for reasons other than taste, aroma, or nutritive value"). Under *Nutrilab*, a substance whose uses do not include taste, aroma, or nutritive value is not a food.

FDA does not believe that the word "food" should be defined any more broadly than it is in the proposed regulation, and the agency specifically rejects the proposal to define "food" as "any substance that is consumed by people for any purpose other than the treatment of disease." Under such an expanded definition, the parenthetical exception for food to the definition of drug in section 201(g)(1)(C) of the act would swallow the rule. Section 201(g)(1)(C) of the act states that "articles (other than food) intended to affect the structure or any function of the body of man or other animals" are drugs. Under the definition of food suggested in the comment, the only products consumed by people that would be considered drugs under section 201(g)(1)(C) of the act would be those intended both to affect the structure or function of the body and to treat a disease. Substances taken to treat a disease are already drugs under section 201(g)(1)(B) of the act, regardless of whether they are foods. The suggested definition of "food" would thus render section 201(g)(1)(C) of the act meaningless. It is a basic principle of statutory construction that a statute should not be construed in such a way as to render certain provisions superfluous or insignificant. *United States* v. *Leonard*, 868 F.2d 1393, 1395–96 (5th Cir. 1989), cert. denied, 496 U.S. 904 (1990).

46. Numerous comments from producers and consumers of dietary supplements expressed concern that the proposed provision represents an attack by the agency against dietary supplements. Some comments maintained that FDA lacks the legal authority to restrict approved health claims on nutritional supplements that are beyond daily diet limits. Other comments asserted that FDA intends to use regulations based on the proposal to ban health claims on dietary supplements wherever the supplements contain a substance above the context of an ordinary daily diet. Other comments stated that the agency would ban the supplements themselves by making them available only by prescription or by limiting the potency of the supplements. A few comments believed that FDA would also ban supplements where they lack a therapeutic effect at levels within the context of an ordinary daily diet. While most of the comments did not specify any particular proposed provisions that could lead to these actions, they strongly protested that any restriction on dietary supplements would infringe on consumers' freedom of choice and would be in conflict with the Proxmire Amendment (21 U.S.C 350) and the 1990 amendments.

As stated above, the DS Act imposed a moratorium on the implementation of the 1990 amendments with respect to dietary supplements. Thus, nothing in these final rules will affect dietary supplements in any way. However, FDA disagrees with the comments' characterization of its proposal and disagrees with the statement that the proposed regulations were in conflict with section 411 of the act (21 U.S.C. 350) (the Proxmire Amendment). Nothing in the proposed regulations would have affected the availability of dietary supplements. Rather, these regulations were intended to regulate claims that may be made for all foods, including dietary supplements.

Nothing in the regulations would necessarily prevent a supplement from bearing a health claim when that supplement contains a level of a substance that exceeds the level achievable in the context of the daily diet. To the contrary, the final rule concerning calcium (where health benefits are provided within the context of the daily diet), for example, which is published elsewhere in this issue of the **Federal Register**, permits a calcium health claim for dietary supplements and requires only that the supplement labeling advise consumers that there is no known benefit from consuming more than 200 percent of the U.S. Recommended Dietary Allowance (U.S. RDA) for calcium.

Section 411 of the act does not authorize health claims for dietary supplements or in any way affect FDA's authority under section 403(r)(5)(D) of the act to regulate such claims. Under section 411(a)(1)(B) of the act, FDA may not classify a dietary supplement as a drug solely because it contains vitamins or minerals exceeding the level of potency that the agency determines is nutritionally rational or useful. Nothing in the proposed regulations would have done so. Absent a claim, FDA will not consider a dietary supplement to be a drug simply because it contains vitamins or minerals at levels above those normally found in food. However, a claim on a product may indicate the product's intended use. If a claim reveals that the product is intended to be used in the diagnosis, cure, mitigation, treatment, or prevention of disease, or to affect the structure or any function of the body (other than food), the product is a drug. (See 21 U.S.C. 321(g)(1)(B) and (g)(1)(C)).

47. Another comment asked for assurance that approved health claims appearing on dietary supplements will not automatically be considered drug claims. The comment noted that section 201(g)(1)(B) of the act exempts approved health claims on foods from consideration as drug claims and stated that dietary supplements should be afforded the same exemption under FDA regulations.

Section 202(b) of the DS Act does permit FDA to approve health claims with respect to dietary supplements. FDA advises that, as provided in section 201(g)(1)(B) of the act, any food, including dietary supplements, for which an authorized health claim is made in accordance with the requirements of section 403(r) of the act, and of the regulations that FDA has adopted to implement that section of the act, is not a drug under section 201(g)(1)(B) solely because its label or labeling contains such a claim. FDA considers this provision to provide the same type of assurance as that in sections 406, 408, and 409 of the act that foods containing substances used in accordance with regulations issued under those sections of the act are not subject to regulatory action under section 402(a)(1) of the act. This provision does not create an exception to the "drug" definition. Thus, a product whose intended use is as a drug will continue to be regulated as a drug.

3. Drugs

48. One comment contended that FDA should permit the use of health claims on over-the-counter (OTC) antacid products containing only calcium carbonate. The comment noted that the preamble to the proposed regulations cited the potential for confusion if health claims were allowed for bulk-fiber laxatives that have not been shown to be useful in lowering cholesterol and for which appropriate labeling for that claim does not exist. The comment asserted that while health claims may be inappropriate for laxatives, such claims would be appropriate for antacids. The comment stated that calcium has been

identified as an essential nutrient which, unlike psyllium, has a defined intake requirement as well as a claim that FDA has proposed to authorize relating to the role of calcium in helping to reduce the risk of developing osteoporosis. The comment asserted that FDA's objection to OTC drugs bearing health claims is not appropriate in the case of calcium-based antacids because antacids have been labeled for years with both food and drug labeling. The comment explained that many antacids bear calcium nutrient content claims with directions for using the products as calcium dietary supplements as well as antacids.

Further, the comment pointed out that, in addition to calcium carbonate, there are several multiple use products currently in the marketplace (e.g., sodium bicarbonate). The comment stated that sodium bicarbonate, marketed under the name "baking soda," is labeled as a baking ingredient, a deodorizer, and an antacid. The comment suggested that FDA approve health claims on drugs under the following conditions: (1) The drug is properly labeled; (2) a health claim has been approved by FDA for an ingredient in the drug; (3) the OTC product meets or exceeds the requirement for a minimum recommended intake of "the natural supplement" as established by regulation; and (4) all labeling is in compliance with the authorizing regulation.

Multiple use products that are both foods and drugs present a difficult set of competing concerns for the agency. Such products are likely to be, like the product that is the subject of the comment, both an OTC drug and a dietary supplement.

Most OTC drug products are developed to address some type of acute physical problem that is expected to be of short duration. If the problem persists, it is important that the person with the problem know that it may be more severe than he or she otherwise thought, and that he or she seek medical attention. Labeling on such products, therefore, includes instructions to use the product for a limited period of time and, if the problem persists, to seek medical intervention. Thus, the time limits on use of the product are important to the health of the users.

Dietary supplements, on the other hand, are developed for inclusion in a daily diet at levels that are consistent with dietary use and may often be consumed throughout most of a person's lifetime. Labeling on dietary supplements contains no instructions for seeking medical intervention or for limiting the duration of consumption of the supplement. Rather, under the 1990 amendments (subject to the DS Act), they will be able to bear nutrient content and health claims, which focus the consumer's attention on the advantages that consuming the product will have in helping the consumer to maintain a healthy diet. Moreover, where the supplement bears a health claim, the claim will contain information about how long-term ingestion of the supplement may promote health.

The comment's reference to baking soda (sodium bicarbonate) as an example of a dual labeled drug/food is not apposite. As a food, baking soda is consumed only as an ingredient in other foods, and it is unlikely that labeling would result in increased consumption of this product. Baking soda is not labeled with either a nutrient content claim or a health claim. Thus, there is little opportunity for consumer confusion presented by this product.

Where dietary levels and therapeutic levels differ (as is generally the case and is in fact the case with antacids and calcium supplements), an apparent conflict is created when both food and drug labeling appear on the same product. In the case of the drug labeling, consumers are given directions for use that involve high consumption during a limited time period. In the case of the food labeling, consumers are given directions for lower consumption with no time constraints. Even though label instructions may identify those directions for food and drug use in separate locations, FDA is concerned that consumers will incorrectly assume that the therapeutic dosage is appropriate for dietary use, and that the directions for food use will undercut the warning in the drug labeling to seek medical care if use persists. Where the labeling is not properly followed, significant adverse consequences may result.

The agency knows of no broad approach that it can use to harmonize a nutrient content claim or a health claim with drug labeling. A drug that is labeled with instructions for use that both limit and do not limit consumption would be misbranded under section 502(a) of the act (21 U.S.C. 352(a)) if it failed to contain a material fact—that is, how to reconcile these conflicting instructions. Therefore, FDA advises that it will tend to view dual claims as misbranding the product.

However, FDA does not believe that it would be appropriate to preclude such claims under all circumstances. Such claims may be permissible if a firm can demonstrate that dual claims can be made in a manner that will neither misbrand the product nor create a safety problem. The agency suggests that anyone desiring to make a health claim or a nutrient content claim that complies with section 403(r) of the act on a product that is both a food and a drug contact the Center for Drug Evaluation and Research, OTC Compliance Branch (HFD–312), FDA, 7500 Standish Pl., Rockville, MD 20855, to discuss whether it would be possible to put such a claim on the product and still comply with the drug provisions of the act.

49. Some comments asserted that FDA should permit the use of health claims on herbs whose only known use is for medicinal effects. A few of these comments objected that the herbs that FDA cited in the preamble of the proposal also have food uses.

As FDA explained fully in the preamble of the proposal (56 FR 60554), Congress clearly intended that the health claim provisions of the 1990 amendments apply only to foods. A product that is intended for medicinal effects, that is, intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease, is a drug and not a food. Thus, there is no basis under the act for FDA to permit health claims for herbs whose only known use is for medicinal effects. Health benefits of such herbs may appear in the labeling only in accordance with the drug provisions of the act. Where herbs have a history of use both as foods and drugs, the context of all of the available information on the intended use of the product will determine whether FDA will regulate the herbs as foods, as drugs, or as both foods and drugs.

In this regard, the agency points out that the relationship of a food or a food component to a disease is quite different from that of a drug. The Surgeon General's report (Ref. 5) points out that, apart from classic disorders resulting from dietary deficiencies of essential nutrients (e.g., pellagra and niacin), it has proved difficult to demonstrate causal associations between specific dietary factors and chronic or other diseases (e.g., dietary fiber and cancer). The report states:

> Development of the major chronic disease conditions—coronary heart disease, stroke, diabetes. or cancer—is affected by multiple genetic, environmental, and behavioral factors among which diet is only one—albeit an important—component. These other factors interact with diet in ways that are not completely understood. In addition, foods themselves are complex; they may contain some factors that promote disease as well as others that are protective. The relationship of dietary fat intake to causation of atherosclerotic heart disease is a prominent example. An excess intake of total fat, if

characterized by high saturated fat, is associated with high blood cholesterol levels and therefore an increased risk for coronary heart disease in many populations. A higher proportion of mono- and polyunsaturated fats in relation to saturated fats is associated with lower blood cholesterol levels and, therefore, with a reduced risk for coronary heart disease.

Because of these complexities, definitive scientific proof that specific dietary factors are responsible for specific chronic disease conditions is difficult—and may not be possible—to obtain, given available technology.

(Ref. 5). Thus a claim that a substance can be used in the prevention, diagnosis, cure, mitigation, or treatment of a disease or symptom is inappropriate on a food: (See § 101.9(k)(1).)

C. Safety

Proposed § 101.14(b)(3)(ii) would require that to justify a claim for a substance that is to be consumed at other than decreased levels, the use of the substance must be shown by the proponent of the claim, to FDA's satisfaction, to be safe and lawful under the applicable food safety provisions of the act.

The preamble of the proposed rule stated further:

> * * * This showing can be based on: (1) A demonstration that the substance is generally recognized as safe (GRAS) within the meaning of 21 CFR 170.30; (2) a listing of the substance as GRAS in 21 CFR part 182 or as affirmed as GRAS in 21 CFR part 184; (3) a food additive regulation; or (4) a sanction or approval granted by FDA or the United States Department of Agriculture prior to September 6, 1958. If the safety and lawfulness of the substance is not expressly recognized in an FDA regulation, the burden will rest on the claim's proponent, as a prerequisite to FDA's evaluation of the health claim, to submit all the scientific data and other relevant information required to demonstrate safety and lawfulness in accordance with applicable petition requirements. FDA will withhold review of the health claim until it is satisfied on these points.

(56 FR 60537 at 60546 through 60547)

50. Many industry comments objected to the safety provisions as proposed. Some of these comments asserted that the 1990 amendments do not require a separate showing of safety for nutrients that are the subject of disease-related claim petitions, and that FDA should not add such a requirement to its regulation. Many comments particularly disagreed with the application of FDA's preliminary safety requirement to dietary supplements and herbs. The comments pointed out that many herbs and supplements have been used for thousands of years with no known ill effects. Requiring further evidence of safety for these products, the comments contended, would be superfluous and expensive. However, other comments agreed with FDA that it would be inappropriate to allow a health claim on a product that contains a substance that is not GRAS, is not the subject of a food additive regulation, or has not received a prior sanction of approval.

FDA believes that the preliminary requirement that substances must be components of food that are safe and lawful must be included in the health claims final rules. Sections of the act enacted by the 1990 amendments cannot be implemented independently of the remaining portions of the act. The act must be considered as a whole, and FDA's responsibility for ensuring the safety of foods is explicitly provided for in other sections of the act (see sections 201(s), 402(a)(1) and (a)(2), and 409 of the act).

This fact is particularly significant because the agency will be specifically providing for the health claims that will be made. In view of this affirmative action, FDA authorization of a health claim places the agency's imprimatur on the claim. It would be a violation of the agency's responsibility under the act to authorize a health claim about a substance without being satisfied that the use of the substance is safe. Furthermore, safety considerations are also of unique importance in the case of health claims because such claims will inevitably change consumption patterns of many Americans.

Even though there is no explicit provision in the 1990 amendments requiring a separate showing of safety, it must be kept in mind that the act "* * * is designed to ensure the safety of the food we eat * * *." Les v. Reilly, ——— F.2d ——— (9th Cir. 1992). This requirement is implicit in the 1990 amendments. Section 403(r)(3)(A)(ii) of the act states that a health claim may be made only for a food that does not contain any nutrient in an amount that increases the risk of a disease or health-related condition that is diet related to persons in the general population, taking into account the significance of the food in the total daily diet. FDA believes that, in addition to requiring establishment of disqualifying levels, this provision evidences a concern by Congress that a substance that is the subject of a health claim be used in a manner that is safe. This concern was reflected in the statements of the sponsors in both the House and the Senate (Refs. 2 and 3).

Further, section 9 of the 1990 amendments states that the amendments "shall not be construed to alter the authority of the Secretary of Health and Human Services * * * under the Federal Food, Drug, and Cosmetic Act * * *." Thus, FDA's responsibility for ensuring the safety of foods has in no way been diminished by the passage of the 1990 amendments.

As a result of the DS Act, herbs and other substances in dietary supplements are generally not subject to the provisions of this final rule. However, to the extent that these substances bear an approved health claim under section 202(b) of the DS Act, they will also bear the agency's imprimatur. To that extent, they will be treated in the same manner as other substances that bear such claims. Other issues with respect to the safety of substances in dietary supplements will be addressed in the rulemaking provided for in the DS Act.

51. Some comments argued that the agency should give full weight to manufacturers' private GRAS determinations in instances where food manufacturers seek to use substances that are not listed by FDA as safe. Some of these comments asserted that if FDA does not recognize private GRAS determinations for fulfilling the preliminary safety requirement, the agency will frustrate Congress' intent to permit health claims, because the GRAS petition procedure is usually quite lengthy, and many GRAS affirmation petitions are pending that are more than 10 years old. Some of the comments requested that if the agency does not recognize private GRAS determinations, FDA should shorten the timeframe for making its GRAS determination or establish an alternate procedure. One suggested that FDA relinquish responsibility for making GRAS determinations to USDA. Another comment suggested that FDA recognize the findings of an independent panel of experts, pending the results of the formal review process.

FDA acknowledges that the GRAS affirmation and food additive listing process can be lengthy. Thus, FDA designed new § 101.14(b)(3)(ii) to provide flexibility with respect to the type of showing of safety that is necessary to make a substance eligible to be the subject of a health claim. GRAS affirmation and food additive listing are but two of the procedures by which a substance may meet this preliminary requirement.

FDA intends to consider the basis of manufacturers' independent GRAS determinations where such determinations are submitted with petitions for health claims and may use its discretion to accept, without formal affirmation, the independent determination of GRAS where FDA believes that such action would be

appropriate. As FDA pointed out in the previous comment, however, the agency would not be fulfilling its responsibilities under the act if it were to permit a substance to be the subject of a health claim without satisfying itself that the use of that substance is safe.

Although FDA will consider all manufacturers' independent GRAS determinations where the bases for such determinations are submitted with petitions for health claims, the agency advises that it will generally not be possible for FDA to judge whether GRAS determinations based on complex scientific evidence are valid within the short timeframes mandated under the 1990 amendments for health claims petitions. Instead, agency agreement with an independent determination that a substance is GRAS will be most likely where the substance is an ingredient, or a component of a food ingredient, that was in common use in food prior to January 1, 1958, in a similar context. However, where such agreement occurs, the agreement does not constitute GRAS affirmation. Instead, the history of common use in food, coupled with the fact that FDA knows of no reason to question the safety of the food ingredient, means that the substance will be treated as if it is an unlisted GRAS substance (as provided for in §§ 170.30(d) and 182.1(a) (21 CFR 170.30(d) and 182.1(a))) in the manner provided for in the food ingredient list in 21 CFR part 182.

In response to comments requesting that FDA relinquish responsibility for making GRAS determinations to USDA, or that FDA recognize the findings of an independent panel of experts pending the results of the formal review process, the agency advises that neither course of action would be appropriate. FDA is charged under the act with the responsibility of protecting interstate commerce from adulterated foods. There is no basis under the act for delegation of this responsibility to other Federal agencies or to individuals outside of FDA.

IV. Validity Requirements for a Claim

A. The Scientific Standard

As proposed, the scientific standard in § 101.14(c) stated:

> * * * FDA will promulgate regulations authorizing a health claim only when it determines, based on the totality of publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant agreement among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.
>
> (1) It must be supported by the totality of publicly available scientific evidence (including evidence from welldesigned studies conducted in a manner which is consistent with generally recognized scientific procedures and principles); and
>
> (2) There must be significant scientific agreement among experts qualified by scientific training and experience to evaluate such claims that this support exists.

(56 FR 60537 at 60563)

In the preamble of the proposal (56 FR 60547), FDA advised that this standard embodies the language in the statutory requirements for conventional food in section 403(r)(3)(B)(i) of the act that there be significant scientific agreement about the support for the claim and the mandate provided in the legislative history of the 1990 amendments that FDA have "a high level of comfort that the claim is valid" (Ref. 1). Thus, the agency will authorize a claim when the evidentiary and review components of the scientific standard are met. However, FDA also stated in the proposal:

> It has been suggested that FDA should allow claims that reflect more preliminary * * * scientific findings so long as such claims are qualified in a way that appropriately reflects the state of the scientific evidence. For example, under this suggestion, FDA would allow a claim such as "Preliminary data show that diets rich in fiber reduce the risk of heart disease," so long as there is significant scientific agreement that this is in fact what the evidence shows. FDA has significant reservations about these types of claims, however, because of their potential to be misunderstood by consumers and therefore to be misleading. The agency is also concerned that such claims will undercut the credibility of the food label. This concern exists despite the fact that because such claims arguably do not assert a [causal] relation between diet and diseases they can never by disproved. FDA requests comments on whether it should authorize these types of claims in implementing the health claim provisions of the act.

(56 FR 60537 at 60552)

52. A number of comments objected that the wording of proposed § 101.14(c)(1) and (c)(2) changes the meaning of the scientific standard presented in section 403(r)(3)(B)(i) of the act. One comment asserted that the proposed provisions treat the totality of publicly available scientific evidence as a separate evidentiary element in showing that the claim is sound, thus distorting Congress' clearly-expressed intent. Similarly, the comment asserted that the language "supported by" in proposed § 101.14(c)(1) "eviscerates" the provisions of the statute because the level of support called for by this requirement is not consistent with the "significant scientific agreement" that the act prescribes. Some comments appeared to interpret the basis of the standard proposed in section 403(r)(3)(B)(i) of the act as being primarily or exclusively the review component, which incorporates the criterion of "significant scientific agreement."

FDA did not intend to change the meaning of the scientific standard presented in section 403(r)(3)(B)(i) of the act through the inclusion of paragraphs (c)(1) and (c)(2) in proposed § 101.14(c). The agency merely intended to clarify that, in accordance with the language of the 1990 amendments, the scientific standard does, in fact, include both a body of evidence component and a review component. However, the agency now recognizes that this attempt to provide greater clarity within the regulatory language itself was unnecessary and, to the extent that it has been interpreted as an attempt to change the meaning of the scientific standard, undesirable. The agency is therefore deleting proposed § 101.14(c)(1) and (c)(2). Without these paragraphs, the wording in new § 101.14(c) is virtually identical to that in section 403(r)(3)(B)(i) of the act.

The wording in section 403(r)(3)(B)(i) of the act and in new § 101.14(c), as amended, clearly establishes two components within the scientific standard. The evidentiary component arises from the inclusion of the phrase "evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles" in the statutory qualification of "the totality of publicly available scientific evidence." This aspect of the standard clearly mandates that the claim be based on a body of sound scientific evidence. The requirement that there be "significant agreement among experts qualified by scientific training and experience to evaluate such evidence * * * that the claim is supported by such evidence" constitutes the separate and distinct review component of the standard.

53. Some comments objected to the standard and suggested modifications. Several comments stated that Congress intended the scientific standard to be one of substantial evidence (i.e., "more than a scintilla and less than a preponderance"). The comments asserted that the 1990 amendments require that FDA adopt such a standard. The comments contended that a standard of substantial scientific evidence, even in the absence of significant scientific agreement, would be in accordance with sound scientific

principles and prevention of consumer fraud. They argued that such a standard would better serve public health through the prompt communication of the health and disease information. Further, other comments objected that the requirement of significant scientific agreement in the proposed standard expands FDA authority beyond legislative intent.

A number of comments maintained that, instead of "significant scientific agreement," FDA should use a scientific standard encompassing different degrees of certainty for different types of health claims. Most industry comments urged FDA to allow health claims based on preliminary evidence if the preliminary status of the claim is truthfully disclosed on the label (e.g., "preliminary data suggest"). Many of these comments contended that such claims would not be misleading and asserted that there was no evidence that the public might misunderstand such claims. Some of the comments asserted that such claims would be consistent with the statutory scientific standard because that standard requires only that there be agreement that the claim is supported by some of the available scientific evidence. Other comments argued that any preliminary study that is sufficiently well-designed and well-conducted should be sufficient to engender "significant scientific agreement" that it supports the health claim being made. Another comment stated that there was no evidence to warrant FDA concern that the public might misunderstand such claims, and that past regulatory policies and court cases involving both FDA and FTC clearly allowed such claims.

Some comments maintained that preliminary claims should be permitted because the benefit to a consumer if a preliminary claim is later proven to be true is significantly greater than the loss if it proves to be false. The comments cited various cases in which preliminary evidence has proven to be correct only after a period of several years. For example, one comment asserted that many lives would have been saved had FDA allowed preliminary health claims regarding cholesterol and heart disease. Other comments expressed concern that one effect of limiting health claims on food labels will be that manufacturers, not being able to assert the dietary characteristics of new foods which fail to meet the new standards, will lose a significant incentive to conduct nutrition research of new food formulations.

A few comments maintained that FDA should permit all preliminary claims, including claims about those nutrient-disease relationships that the agency proposed not to authorize, because those claims that FDA proposed to permit are actually preliminary claims. The comments explained that the claims that FDA proposed use qualifying words such as "may," as in the phrase "may help to reduce disease risk," rather than absolute claims.

However, other comments, primarily from the health care and regulatory sectors, favored the scientific standard as proposed and strongly opposed permitting preliminary health claims, stating that preliminary evidence does not meet the scientific standard of the 1990 amendments. The comments pointed out that one of the main purposes of this new standard is to prevent the type of questionable health claims that have grown all too common in recent years. They noted that if a health claim is still the subject of conflicting reports, it is entirely inappropriate for the food label. Many comments suggested that, even with a disclosure statement as to the preliminary nature of the claim, many consumers would be misled, as the word "preliminary" does little to lessen the impact of a claim, and many consumers would not understand that the findings could be disproved later. Other comments stated that allowing preliminary claims could open the floodgates to a large number of partially supported claims, thereby undercutting the credibility of the valid health claims on food labels.

FDA does not have authority to modify the scientific standard for health claims. Section 403(r)(3)(B)(i) of the act directs FDA to promulgate regulations authorizing health claims only if it determines:

> * * * based on the totality of publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

FDA has incorporated this standard into its regulations. Thus, the requirement objected to by several of the comments, that there be significant scientific agreement that the claim is supported by the publicly available evidence, derives directly from the act.

FDA does not agree that a "substantial evidence" standard, as described by one comment, was intended by Congress, or that the agency is under any obligation to adopt such a standard. Congress adopted the scientific standard for health claims in section 403(r)(3)(B)(i) of the act from FDA's February 13, 1990, reproposal (55 FR 5176). Congress had the opportunity to adopt a different standard, to modify FDA's proposed standard, or to equate the standard with the substantial evidence standard, but it did not. The standard adopted permits FDA to make case-by-case determinations on the scientific validity of a claim, giving greater weight to studies that it finds more persuasive (Ref. 1). Congress intended the scientific standard to be "strong" and for the agency to have a high level of confidence that a claim is valid. Id. Of course, in applying this standard, FDA will act in a manner that is fair and neither arbitrary nor capricious.

In determining whether preliminary evidence would provide the basis for a health claim under this standard, FDA looked carefully at the language of the act and its legislative history. The legislative history establishes that Congress' intent was to ensure the scientific validity of authorized health claims. (See statement of Rep. Waxman; Ref. 4, H5844: "What we have sought to do is to permit health claims but only health claims based on *scientifically valid* information * * *" (emphasis added).) If Congress' aim had been solely to prohibit false or misleading claims, it could have left FDA with its authority under sections 403(a) and 201(n) of the act. Instead it added section 403(r) of the act to ensure not only that claims are not false or misleading, but also that they are scientifically valid.

The fact that Congress adopted in section 403(r)(3)(B)(i) of the act the standard that FDA set out in its reproposed rule on health messages is significant in other respects. In the reproposal, the agency stated that it would not accept preliminary support for a label statement (55 FR at 5180). FDA proposed to permit only claims "supported by a sound body of scientific evidence" (55 FR at 5180). Congress adopted FDA's proposed standard without stating that it was expanding the standard to include preliminary claims; instead it stated that it was adopting the same standard (Ref. 1).

Allowing claims based only on preliminary data would thus not be consistent with the terms of the statute and indeed would undercut the statutory scheme. The standard for permitting a health claim requires that the claim be supported by the totality of publicly available scientific evidence, and that there be significant scientific agreement among qualified experts that this support exists. A claim based on

preliminary data would not reach the threshold of scientific validity required by this standard. It is not sufficient that there simply be agreement among scientists that a statement accurately characterizes the preliminary nature of the data, or that preliminary data could be interpreted in the way stated. Authorizing a claim in such circumstances would produce claims that are little more than hypotheses. While such claims might not be false or misleading, they would not be scientifically valid. Under the statutory scheme, a health claim is to describe the scientifically established relationship between a nutrient and a disease or health-related condition, not the state of the evidence that might support such a claim. FDA is to focus on the state of the evidence in determining whether the claim is valid. Thus, preliminary claims are not permissible under the act.

FDA does not agree that its past regulatory practices dictate that it permit preliminary or controversial health claims. The 41 year-old consent decree in *United States* v. *Mytinger & Casselberry*, referenced by one comment, is not relevant to the current situation and has been superseded by subsequent developments. With the 1990 amendments, Congress added the specific requirement to the act that any health claim on a food must not only not be misleading but also must be scientifically valid. The agency does not have the authority to permit preliminary or controversial health claims that are qualified by an explanation that a difference of scientific opinion exists. Moreover, the agency does not consider itself in any way obligated to follow the FTC consent decree referenced by a comment.

While FDA concludes that preliminary claims are not consistent with the act, that does not mean that the agency concludes that any qualification in a health claim would bar its use. Elsewhere in this issue of the **Federal Register**, FDA is authorizing health claims on food labels that are qualified claims. FDA is authorizing these claims because it finds that they meet the standard of scientific validity. For each of the claims that FDA is authorizing, there is significant scientific agreement that there is a high probability that a reduction in risk of disease will occur.

Further, absolute claims about diseases affected by diet are generally not possible because such diseases are almost always multifactorial. Diet is only one factor that influences whether a person will get such a disease. For example, in the case of calcium and osteoporosis, genetic predisposition (e.g., where there is a family history of fragile bones with aging) can play a major role in whether an individual will develop the disease. Because of factors other than diet, some individuals may develop the disease regardless of how they change their dietary patterns to avoid the disease. For those individuals, a claim that changes in dietary patterns will reduce the risk of disease would be false. Thus, health claims must be free to use the term "may" with respect to the potential to reduce the risk of disease. However, use of this term would not be appropriate for health claims on food labeling where significant scientific agreement does not exist that there is a high probability that a reduction in disease risk will occur.

Furthermore, Congress clearly concluded that there is a great deal of consumer confusion over health claims on food labeling (Ref. 1). FDA believes that much of the confusion results from claims based on preliminary data, and the agency believes that comments opposed to permitting preliminary claims are correct in their assessment that many consumers do not understand that preliminary claims are based on science considerably weaker than claims based on science about which there is a significant amount of scientific agreement. Also, FDA agrees with those comments maintaining that allowing preliminary claims would open the floodgates to a large number of partially supported claims, thereby undercutting the credibility of valid health claims on food labels and of the food label itself. FDA believes that health claims must be credible if they are to be useful to consumers.

If FDA were to focus only on the impact of a single preliminary claim, arguments that benefits to consumers from permitting that claim where it might be true would outweigh losses where the claim later proved to be false might have merit. However, FDA must focus on the ultimate impact that permitting a multitude of preliminary claims would have on public health and on public confidence in the food label. That ultimate impact could easily involve a perception among many consumers that health claims and food labels are not reliable. To the extent that consumers do not change their dietary patterns to reduce their risk of disease, they will be less healthy, and there will be needless deaths from disease as well as costs to the national economy. Thus, FDA disagrees with comments asserting that preliminary claims would be in the best interests of consumers.

Further, FDA doubts the accuracy of comments asserting that manufacturers will lose significant incentive to conduct research on new food formulations. The agency believes that the high credibility of FDA sanctioned claims and their impact on consumer purchasing decisions will prove to be sufficient incentive to continue such research. Further, if the agency were to permit almost all health claims of a preliminary nature, the value of such claims as marketing tools would surely be considerably weakened as consumers lose faith in all claims.

Of even more importance, however, is the fact that, even though FDA's approach to permitting health claims may not permit as many claims as some firms desire, FDA's approach will provide for scientifically valid health claims. Over time, FDA's approach is likely to prove to be of far greater value in promoting good public health than permitting almost all preliminary claims. Further, FDA's approach does not require absolute proof of the validity of a claim. Instead, this approach requires that there be sound science to support the claim.

54. A number of comments called for a consensus among scientists prior to the approval of a claim.

The legislative history of the 1990 amendments makes clear that Congress did not intend, in calling for significant scientific agreement about the support for a claim, to require that such agreement represent a full consensus among scientists. The House Report (Ref. 1) states: "* * * the standard does not require that there be a unanimous agreement among experts. Instead there must be a significant agreement among experts, but it does not require that every expert in the field approve or agree with the claim."

The agency believes that a consensus, if defined as unanimous agreement among scientists about the validity of a particular claim, would be difficult to achieve, and that a standard requiring consensus would therefore prove impracticable. The agency is concerned that the stringent requirement of consensus would cause many valid health claims not to be approved and, by restricting such claims, would counter Congress' intent that health claims supported by a significant scientific agreement be made available to consumers. In view of these concerns, and in conformity with the expressed intent of Congress and with the statutory language of the 1990 amendments, the agency will not require that claims be supported by a consensus among scientists.

55. Several comments objected that the scientific standard, particularly the phrase "significant scientific agreement," is vague and subjective. One comment asked for clarification as

to the degree to which this phrase is qualitative or quantitative in nature and noted that a standard of evidence must be specific and consistent. Several comments suggested that the manner in which FDA applied the scientific standard is overbroad.

The agency is sensitive to the comments' perception that the scientific standard, particularly the phrase "significant scientific agreement," is subjective. The agency believes, however, that any standard involving the evaluation of scientific evidence and the opinions derived from that evidence must be somewhat subjective. FDA, in choosing not to define "significant agreement" among experts in the November 27, 1991, proposal (56 FR 60548), noted that each situation may differ with the nature of the claimed substance/disease relationship. The agency believes that in deciding whether significant scientific agreement about the validity of a claim exists, it is necessary to consider both the extent of agreement and the nature of the disagreement on a case-by-case basis. The agency is concerned that if scientific agreement were to be assessed under any quantitative or rigidly defined criterion, the associated inflexibility of such a criterion might cause some valid claims to be disallowed where the disagreement, while present, is not persuasive.

The House Report (Ref. 1) affirms the intended flexibility of the "significant scientific agreement" standard by pointing out that, in reviewing scientific studies, FDA may give greater weight to the studies that it finds more persuasive. The House Report also clarifies that the overriding consideration in assessing whether to authorize a claim should be the Secretary's level of comfort about the validity of the claim. Id. The agency believes that this clarification provides clear guidance for the application of the standard.

56. Several comments suggested that FDA should look to the new drug provisions in section 505 of the act (21 U.S.C. 355) for direction in assessing significant agreement with the proposed validity requirement and suggested that the degree of scientific agreement needed for health claims approval should be significant but less than that necessary for approval of a new drug application.

FDA agrees that the scientific standard for health claims is less stringent than the requirements for approval of a new drug. In the case of a new drug, section 505(d)(5) of the act provides that the Secretary shall refuse to approve an application for approval of such a drug where there is a lack of substantial evidence that the drug will have the effect that it purports or is represented to have under the conditions of use prescribed, recommended, or suggested in the proposed labeling thereof. The term "substantial evidence" is not, in and of itself, a particularly stringent standard. Section 505(d) of the act provides, however, that the term "substantial evidence" means evidence consisting of adequate and well-controlled investigations, including clinical investigations (human studies conducted in a controlled clinical setting), by experts qualified by scientific training and experience to evaluate the effectiveness of the drug involved, on the basis of which it could fairly and responsibly be concluded by such experts that the drug will have the effect it purports or is represented to have under the conditions of use prescribed, recommended, or suggested in the labeling or proposed labeling thereof. (In identifying the source of substantial evidence, the law limits the kinds of studies that can be used. Even this high standard, however, has a degree of flexibility.) Based on this statutory direction, the agency has identified a number of characteristics that are present in "adequate and well-controlled" studies in 21 CFR 314.126.

However, section 403(r) of the act does not mandate requirements as stringent as those for drugs in section 505(d)(5) of the act. Section 403(r) of the act does not reference substantial evidence, adequate and well-controlled investigations, or clinical investigations. To the contrary, section 403(r) of the act contains more flexibility than the drug provisions of the act by providing FDA with authority to authorize claims based on "scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant agreement among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence" (section 403(r)(3)(B)(i)).

The legislative history of this section of the act evidences a concern by Congress that health claims should not necessarily be restricted to the stringent evidence necessary to support a drug claim. H. Rept. 101–538 states: "Under this standard, the Secretary must review all the scientific evidence available that is pertinent to a claim." (Ref. 1).

In debate preceding passage of the 1990 amendments, the sponsors of the bill raised concerns as to whether food claims should not be subject to a more flexible standard than drug claims. For example, in the July 30, 1990, Congressional Record (H5844) (Ref. 3), Congressman Waxman stated:

> And then there is the issue of health claims. Prior to the mid-1980's, health claims were simply not permitted. A health claim on a food product turned that food product, in a legal sense, from a food to drug because if the health claim were made, then the product had to go through the approval process at FDA to show the efficacy of that claim was valid, the same as would be required by a pharmaceutical.
>
> That was an awfully stringent requirement.

Further, on October 26, 1990 (Ref. 3), Congressman Madigan, the other House sponsor of the 1990 amendments, stated:

> Neither Federal regulation nor industry efforts have kept pace with scientific knowledge about diet and nutrition. This bill is an effort to remedy this situation while allowing FDA sufficient flexibility to modify the rules when valid, new scientific information is presented. Given increased awareness and advances in our scientific knowledge on the relationship between diet and health, this legislation is very timely.

Consistent with this flexibility, FDA is not now prescribing a specific set, type, or number of studies as being necessary to support a health claim. The agency will consider all relevant data on a topic, including clinical studies, epidemiological data, and animal studies. Of course, the type, quality, and relevance of a study from which data are derived have an important bearing on how much weight is placed upon the data. For example, FDA will give the greatest weight in its evaluation to well-designed studies conducted with human subjects. Data from laboratory studies using animals, in vitro tests, and chemical analyses of the food substance may be useful, however, in providing an understanding of the nature of the relationship between the substance and the disease or health-related condition.

In the preamble to the proposal (56 FR 60537 at 60548 through 60549), FDA drew heavily on chapter two of the Diet and Health report (Ref. 6) for a discussion of how it will evaluate the studies that are submitted on the impact of intake of a substance on health. Interested persons are referred to that preamble discussion for further information about how the agency intends to apply the validity standard in new § 101.14(c).

In summary, FDA sees the standard for health claims as different from the standard for establishing the effectiveness of a new drug. The agency is not now establishing any minimum data requirements under this standard, although the agency might find it appropriate to do so in the future as it

gains more experience under the health claims regime. Rather, the agency will review all available scientific evidence that is pertinent to a claim and decide whether, on the basis of that evidence, the characterization of the relationship of a substance to a disease or health-related condition that is presented in the claim is scientifically valid.

B. Assessment of Conformity to Scientific Standard

1. General

57. A few comments expressed concern about specific types of studies that FDA advised that it would consider in evaluating health claims. One comment objected that human studies in general would not be very useful. Another comment objected that human studies based on non-U.S. populations that exhibit consistent results may not be useful. Another comment noted that case-control and cohort studies based on the U.S. population are often not powerful enough to detect diet-disease relationships because the range of nutrient intakes within the population is too narrow. However, most comments agreed with the agency's intention not to prescribe a specific set, type, or number of studies as being sufficient to support a disease-related claim, and with its statement that it will "seek to avoid the pitfalls of inflexible adherence to rigidly defined criteria" (56 FR 60548).

The statutory language of section 403(r)(3)(B)(i) of the act is specific in directing the Secretary to consider the totality of publicly available scientific evidence. FDA cannot, therefore, and would not be inclined to, exclude any scientific evidence from consideration in assessing the validity of a claim. The agency recognizes, however, that the evidence relating to a particular claim may vary in its usefulness, and that some types of studies may be more probative than others in establishing the validity of particular nutrient-disease relationships. The agency will consider, therefore, as it stated in the November 1991 proposal (56 FR 60537 at 60548), the type, quality, appropriateness of design and relevance of each of the studies and of the other information that together constitute the totality of scientific evidence when assessing the validity of a claim. The agency will evaluate the strengths and weaknesses of each individual study and weight it accordingly in reaching a decision about the validity of a particular claim.

58. Other comments urged FDA to consider with fairness any proposed health claim that relies on data derived from non-Western cultures.

The agency advises that it will consider the evidence submitted in support of a claim on its scientific merits and in the context of the totality of available evidence. It will not underrate any study on the basis of its cultural or geographic origin. Evidence in support of a proposed health claim, however, will attain value in direct proportion to the significance in the U.S. population of the effects of the disease or health-related condition addressed by the claim.

2. Dietary supplements

59. Many comments asserted that FDA should establish a more lenient standard for substances in dietary supplements. Some of these comments argued that such a standard is mandated by Congress and cited the statement of Senator Hatch, one of the primary authors of the 1990 amendments, that "a more lenient standard for dietary supplement[s] is envisioned." (Ref. 2). Other comments argued that the standard should be sufficiently lenient to permit marketing of supplements without any labeling restrictions. Some of these comments argued that dietary supplements needed no stringent requirements because supplements could be adequately regulated under the regulatory regime of a label needing to be truthful and not misleading under section 403(a)(1) of the act. A number of comments asserted that the same standard effectively renders section 403(r)(5)(D) of the act superfluous. Some comments asserted that, by not adopting a more lenient standard, FDA would restrict the amount of health information available to consumers and stated that such information is important to consumers in deciding which products to buy. A number of comments asserted that the same standard for supplements is counter to the intent of the 1990 amendments because Congress intended to make more, rather than less, information about the health benefits of foods available to consumers.

However, other comments agreed with FDA's proposal to use the same scientific standard for dietary supplements that the act provides for conventional foods. One comment noted that it is especially important to place dietary supplements under the same standard because they are marketed mainly on the basis of their purported health benefits. Another pointed out that the proposed standard will facilitate purchasing decisions for consumers by reducing fraudulent labeling claims.

A few comments contended that FDA should establish a more stringent standard for substances in dietary supplements. One comment asserted that FDA has adequate authority to do so and asserted that the legislative history of the 1990 amendments supports a more stringent standard. The comment stated that FDA recognized, when it proposed not to authorize a health claim for omega-3 fatty acids in Docket No. 91N–0103 (56 FR 60663, November 27, 1991), that it does make a difference whether one receives nutriment from food or from pills. In that document, the comment maintained, FDA asserted that benefits have been shown for fish but not for omega-3 fatty acids.

Under the DS Act, there is a moratorium on the implementation of the 1990 amendments with respect to dietary supplements. Therefore, FDA is not adopting a standard to implement section 403(r)(5)(D) of the act. The agency will adopt a standard in accordance with the procedures established in the DS Act. However, FDA has carefully considered these comments and, in response, would make the following observations.

Although Congress did convey flexibility in resolving this issue to FDA, and one sponsor did state that this flexibility should be used to establish a more lenient standard, as the agency explained in the preamble of the proposal (56 FR 60537 at 60539 through 60540), the legislative history concerning section 403(r)(5)(D) of the act makes clear that Congress did not intend to require that the agency adopt a different standard for these products (Refs. 2 and 3). Instead, the exemption on its face gives the agency the discretion to adopt a scientific standard respecting the validation of claims for supplements, regardless of whether the standard is more lenient or more stringent (Ref. 3). The exemption gives the agency the same discretion with respect to establishing a procedure under which claims may be made.

The statement of House Floor Managers (Ref. 3), addresses section 403(r)(5)(D) of the act by stating, in part:

> The Senate version of the bill, which we are voting on today, retains this standard for all foods except vitamins, minerals, herbs, and other similar nutritional substances (referred to below as "vitamins"). The bill requires that vitamins that include claims defined under section 403(r)(1)(B) shall be subject to a "procedure and standard" defined by the Secretary in regulations that require an evaluation of the validity of the claim. The FDA 's given the discretion to define both the procedure and the standard because the principals in the Senate could not agree on the appropriate procedure or the appropriate standard.

It is obvious from the language that the agency could adopt the same procedure and standard that Congress has adopted for disease claims on food other than vitamins; it is also obvious that it could adopt a stronger standard for vitamins, minerals, herbs, and other similar nutritional substances.

In addition, the Metzenbaum-Hatch managers' statement in the Senate (Ref. 2) addresses section 403(r)(1)(B) of the act by stating, in part: "The purpose for the different handling of conventional food products and dietary supplements is to provide the Secretary flexibility in the development of the procedure and standard for health claims for dietary supplements."

Thus, both the Senate and the House of Representatives agreed that FDA has the flexibility to adopt the standard and procedure for dietary supplements that appears appropriate to the agency. As pointed out by the comments, Senator Hatch left no question about his position that FDA should use this flexibility to adopt a more lenient standard. However, other members of Congress were equally clear about their position that FDA should not adopt a more lenient standard. In the October 24, 1990, Congressional Record, (Ref. 2), Senator Metzenbaum, the other primary author of the Senate amendments, stated:

* * * It is my view that there is no reason to do anything other than utilize the same procedure and standard for dietary supplements.

Whatever approach the Secretary takes, he must establish a system that evaluates the validity of health claims for dietary supplements. The system must be based on the same considerations that guide other agency decisions: public health, sound scientific principles and consumer fraud.

Further, the House of Representatives clearly did not support a more lenient standard for dietary supplements. The statement of House Floor Managers that appears in the October, 26, 1990, Congressional Record (Ref. 3) states:

* * * Whatever approach the agency takes, it must adopt a system that evaluates the validity of any disease claims made with respect to these substances. Its system must be based on considerations of public health and consumer fraud. As in every similar decision made by the agency today, we fully expect that the agency's evaluation of disease claims made with respect to vitamins will be based on sound scientific principles.

There is a great potential for defrauding consumers if food is sold that contains inaccurate or unsupportable health claims. The potential is just as great for vitamins as it is for other products. In our view, vitamins and other substances covered by this provision should be subject to at least as strong a standard as is applicable to other foods that contain claims that the food will treat a disease or health condition.

Thus, some members of Congress opposed a more lenient standard for dietary supplements. However, it also seems that assertions that Congress supported a more stringent standard in the legislative history of the 1990 amendments are not well-founded. The above-mentioned statements on a more stringent standard were included in the legislative history to demonstrate that one could be established, if appropriate.

The agency will consider this legislative history together with the legislative history of the DS Act in proposing rules to implement the 1990 amendments, with respect to the DS Act. The agency notes that if it were to adopt a more lenient standard and procedure for supplements, there might be a significant potential for consumer confusion when confronted with a situation in which there would be health claims for substances when they are present in supplements but not when they are present in conventional foods. If there is reason to conclude that this would not in fact be the case, FDA urges interested persons to come forward with evidence to support such a conclusion during the rulemaking mandated by the DS Act.

The Managers Report on the DS Act (Ref. 34) states that among the policy goals of the DS Act is to assure the public that health or disease-related claims for dietary supplements are properly supported. In the rulemaking under the DS Act, FDA will try and determine what proper support should incude. In particular, the agency is interested in why the standard for the scientific validity of health claims in section 403(r)(3)(B)(i) which applies by law to claims for all substances for which claims are made except for those in dietary supplements, is not also appropriate for substances in dietary supplements.

The agency also points out that it did not tentatively conclude in the omega-3 fatty acids proposal that it makes a difference whether one receives nutriment from food or from pills, as the comment suggested. While FDA did state in the summary of that docket that there is inadequate evidence to support a beneficial relationship between reduced risk of coronary heart disease and increased consumption of omega-3 fatty acids, and that there is some evidence that benefit may be gained through the consumption of fish, the agency noted that benefits attributed to fish could not necessarily be ascribed to the presence of omega-3 fatty acids. The example, therefore, does not show that a substance is any more beneficial when it is in a conventional food than when it is not in a conventional food.

60. A number of comments suggested that the agency should adopt a separate mechanism for evaluating the validity of claims for herbs. Under the suggested mechanism, an oversight committee would appoint an expert panel that would consist of a director and at least four scientists with training and experience related to herbal and botanical products. (FDA would participate as a nonvoting member.) The panel could hire outside consultants. The committee, which would be charged with the responsibility of reviewing all health claims petitions pertaining to herb or botanical components, would relieve FDA of all responsibility for initial review of these petitions. Such petitions would not be permitted to be submitted directly to FDA. The expert panel that was selected by the committee would conduct an evaluation of scientific data pertaining to the requested claim, subject the evaluation to peer review, and prepare a final recommendation about the claim. The recommendation and all supporting documents would then be forwarded to FDA, and the agency would be permitted 120 days to approve, disapprove, or modify the report. Under draft regulations submitted by one of the comments, there would be a codified presumption in favor of the committee recommendation.

The comment asserted that this mechanism for evaluating petitions would not involve a transfer of the agency's authority and obligation to enforce the act because the final authority for decisions rests with FDA. Further, the comment asserted that there is precedent for the requested mechanism in FDA's past use of reviews of food and cosmetic ingredients that have been prepared by the Federation of American Societies for Experimental Biology (FASEB) and the Cosmetic Ingredient Review (CIR).

Although the DS Act establishes a moratorium on the implementation of the 1990 amendments with respect to dietary supplements of herbs, the agency considers it appropriate to respond to this comment. FDA believes that the mechanism suggested by the comment would involve a significant transfer of agency authority for the control of health claims on herbs, and there is no basis under the act for such a transfer. Although the comment asserts that such a transfer would not take place by maintaining that the final authority for decisions rests with FDA, the assertion is not correct. Because of the codified provision providing that there would be a presumption in favor of the committee recommendation, the agency would be obligated to prove that

the committee was wrong or else it would be required to follow the committee's recommendation. Under such circumstances, FDA could be forced to propose to authorize a health claim that the agency believed, but was unable to prove, was not valid. Thus, there would, in fact, be a significant transfer of authority under the requested mechanism.

Further, there is no precedent for the requested mechanism in FDA's use of FASEB and CIR reviews of food and cosmetic ingredients. Neither type of review created a presumption in favor of the review recommendation. Also, FDA has never required that petitions pertaining to food and cosmetic ingredients be submitted for such reviews. With respect to FASEB reviews, FDA contracted for these reviews as part of its GRAS review in the early 1970's and then once to update information on sulfiting agents. FASEB only submitted a recommendation as to whether, and what, uses of a substance were GRAS. FDA conducted its own review of the evidence and was free to elect to use the FASEB review as it saw fit.

With respect to CIR reviews, such reviews are used primarily by industry to make self-determinations of cosmetic ingredient safety. The agency may, or may not, comment on any CIR review. Even where FDA comments on a CIR review, there would be little likelihood that agency rulemaking would result. In situations where such a review does serve as a stimulus for a rulemaking proceeding, the review would not be the sole reason for the proceeding. The agency fully retains its enforcement authority in both situations.

Moreover, the committee suggested by the comment would be subject to the Federal Advisory Committee Act (5 U.S.C. App. 2). The burdens imposed on an agency by this statute are heavy. FDA has limited resources for advisory committees. While the agency may, on occassion, use advisory committees as part of the health claims process, it believes that it would be an inappropriate expenditure of those limited resources to commit them to the committee suggested by the comment.

Of course, both the conventional food and dietary supplement industries may, if desired, work through committees in preparing well-supported petitions for submission to FDA, and FDA will cooperate with such committees at a scientific level by explaining the agency's requirements to them and sharing publicly available information. However, the agency would not require firms to use such committees, and FDA would still have the ultimate obligation of determining whether the petitioned-for claim is scientifically valid. To clarify that the agency will consider all recommendations by such committees, FDA has revised provisions of new § 101.70(b) to provide that information that is submitted with petitions may include any findings, along with the basis of the findings, of an outside panel with expertise in the subject area at issue. While the agency will consider any findings of a panel included in a petition, the agency will not use that panel to make its decision.

61. Some comments asserted that in addition to the proposed regulatory framework for evaluating health claims, which involves permitting supplement claims on the same terms as for conventional foods, FDA should also subject dietary supplements to an alternative involving a different level of validity substantiation and a different procedure. Under the alternative procedure, claims for which there is substantial scientific evidence but not yet significant scientific agreement would have to undergo a certification and notification procedure rather than rulemaking proceedings. Under the alternative, claims could be made for supplements so long as: (1) The claim expressly discloses the absence of scientific agreement as to the relationship, (2) the manufacturer provides FDA with a fully documented certification by a panel of at least three qualified experts that there is substantial scientific evidence supporting the claim, and (3) FDA does not disapprove the claim within 90 days of receipt of the certification. (When additional information is needed, the 90 day period could be extended an additional 45 days.) Under the alternative, FDA would have an opportunity to participate in the selection of the expert panel.

Given the moratorium on the implementation of the 1990 amendments established by the DS Act, the agency is reserving making a detailed response to these comments at this time. The Managers Report on the DS Act (Ref. 34) states that FDA may wish to propose new rules or to repropose rules under section 403(r)(5)(D) of the act. FDA will consider these comments in deciding what action to take with respect to section 403(r)(5)(D) of the act in responding to the DS Act.

V. General Labeling Requirements

Proposed § 101.14(d)(1) provides that when FDA determines that a health claim is valid, the agency will propose a regulation in part 101, subpart E to authorize the use of the claim. Further, the provision states that if the claim pertains to a substance not provided for in § 101.9 or § 101.36, FDA will propose amending those regulations to include declaration of the substance. FDA points out that § 101.9(a) requires that where a claim about a nutrient is made, the nutrition labeling information shall include appropriate information about that nutrient. Proposed § 101.36(a) also would require nutrition information on dietary supplements. However, given the moratorium established by the DS Act, FDA is not adopting § 101.36 at this time. FDA has deleted the reference to that section from § 101.14(d)(1).

62. Several comments argued that FDA should not permit firms to place any health claims on the labels of conventional foods or of dietary supplements.

Through enactment of section 403(r) of the act, Congress has mandated that firms be permitted to place health claims on food labels when FDA finds that the claims are valid and establishes regulations authorizing their use. Although the comments cited a wide variety of reasons to support their objections, FDA is not addressing these reasons because the 1990 amendments settled this issue. The agency has, therefore, not made any changes in response to these comments.

A. Consistency with Summary of Scientific Information and Model Health Claim

Proposed § 101.14(d)(2)(i) stated that all label or labeling statements about the health benefit that is the subject of the health claim shall be based on, and consistent with, the conclusions set forth in the summary of scientific information and model health claims provided in regulations in part 101, subpart E.

63. Some comments urged FDA not to allow manufacturers to paraphrase an established model health claim. These comments stated that claims should be repeated in the same way on each qualifying food product to ensure that only one clear message is being given to consumers. One of these comments cautioned that consumers faced with health claims stated in a wide variety of ways will be confused about the possibility of differences among the claims. Another suggested that in light of the practical inability of FDA to police varying wordings for accuracy, the only way to ensure that claims are an accurate representation of the facts is to require that agency-drafted claims be used. The comment noted that although the 1990 amendments did not specifically contemplate mandatory FDA-created wording for the health

claims, section 403(r)(3)(B)(iii) of the act could be interpreted to allow such an approach on the basis that the agency wording is the only one that "enables the public to comprehend the information provided in the claim."

However, other comments maintained that manufacturers should not be held to the specific language in the model health claims and asked that the regulations be amended to specifically state that label claims need not be identical to the model claim language. The comments explained that the model claims are too complex to be meaningful to consumers and expressed concern that the proposed requirement for consistency might be interpreted in such a rigid manner that effectively only the model claim would be permitted.

FDA does not believe that the 1990 amendments allow the agency to prohibit manufacturers who wish to place a health claim on a product from paraphrasing language in the model claim. Section 3(b)(1)(A)(vii) of the 1990 amendments prohibits FDA from requiring persons to secure agency approval before placing a health claim on a product, provided that the claim is in compliance with the applicable regulation. The House Report (Ref. 1), states that this section "makes it clear that the regulations will not require premarket review of each claim; they will only require that the claim be consistent with the terms and requirements of the regulations." The agency believes that it is possible to paraphrase a model health claim while remaining consistent with the terms and requirements of the regulations permitting that claim. This position is similar to agency policy that permits the use of terminology other than that established in a final OTC drug monograph in labeling of an OTC drug product to describe indications for use (51 FR 16258, May 1, 1986). Consistent with that policy for OTC drug labeling, the agency believes that the goal of ensuring scientifically valid, truthful, and nonmisleading labeling without inhibiting effective consumer communication does not require exclusive use of language in a model health claim. The model language along with other requirements for that claim will, nevertheless, provide the standard for measuring the accuracy of alternative language developed by food manufacturers for their products because FDA has included all mandatory labeling elements of a health claim in the model claim. Of course, manufacturers should recognize that a paraphrased health claim that fails to convey all the mandatory elements of the claim will subject a product to regulatory action.

Section 403(r)(3)(B)(iii) of the act does not require the verbatim use of the agency's model health claims. The provision states that the agency must require in a regulation authorizing a health claim that the claim be stated in such a way as to allow the public to comprehend the presented information and to understand the relationship of the substance to the disease or health-related condition, the significance of the substance in affecting the disease or health- related condition, and the significance of the information in the context of the total daily diet. The agency's model wording of a health claim is likely not to be the only way in which one can convey all the required information.

Although FDA agrees that manufacturers should not be held to the specific language in the model health claims, the agency does not believe that it is necessary to state this fact in the regulations. Just as some could misinterpret the proposed codified requirement that claims be "consistent with" model claims, others could misinterpret a provision stating that claims "need not be identical to the model claim language." Thus, FDA has revised new § 101.14(d)(2)(i) to require that labeling statements conform to the conclusions set forth in the regulations in part 101, subpart E without any specific reference to provisions contained therein.

64. Some comments contended that FDA's proposed regulations would require too much information in health claims, and that the appearance of so much information in a health claim would confuse consumers. Some of these comments suggested that this confusion could thwart FDA's goal of educating the public. Others asserted that, rather than trying to clear up their confusion, many consumers would simply assume that the product is unhealthy for them and choose products that did not bear the lengthy claims. One of these comments stated that the calcium/osteoporosis claim was, according to computer analysis, so complex that a "fourteenth-grade" reading level was required to properly understand it.

Another comment objected that the proposed policy of codifying "all" effects of a nutrient on a condition or disease would lead to the inclusion of effects that were of tangential importance or that were not the subject of significant scientific agreement. Instead, the comment stated, FDA should limit its description to significant effects on which there was such scientific agreement.

However, other comments agreed with FDA's proposal that health claims should include information on factors that affect the nutrient-disease relationship (e.g., exercise). One consumer advocacy organization strongly asserted that it is important that nutrient intake not appear to be the sole factor in matters affecting the risk of disease when other factors are considered to be of similar importance. The comment stated that use of such language as "one of several factors" and "can help" in health claims will help the public to understand that the nutritional characteristics of the foods bearing claims are not "cure-alls" for the disease/health condition mentioned.

FDA agrees that consumers should be presented with health claim information in a clear, nonconfusing manner, and the agency realizes that there is a limit to the amount and complexity of information that can be presented in a health claim. However, the agency believes that it must require enough information in a health claim to ensure that consumers understand that factors other than dietary intake of the nutrient may bear on the substance-disease relationship. Given these imperatives, the agency is faced with the difficult task of determining what information is necessary in a claim, and what information is not.

FDA has reviewed the requirements for the health claims that it is authorizing elsewhere in this issue of the **Federal Register** to determine whether they call for the inclusion of information in the claim that is not absolutely necessary to allow the consumer to understand the claims in the context of a total daily diet. FDA has deleted information that is not necessary from the list of mandatory information and instead has listed this information as information that a manufacturer may opt to include in a health claim. FDA will take a similar approach in the future. FDA believes that its regulations in part 101, subpart E now represent an acceptable balance between the consumer's right to understand the full context of the claim and the manufacturer's concern over claim length. By delineating the information that is mandatory and optional in a claim, FDA is relieving manufacturers from having to include information that is of tangential importance but allowing those who wish to use the information to do so without violating the authorizing regulation.

As for the comments that asserted that the sentence structure and phrasing of

the model claims are too complex, the agency has sought to minimize complexity but has found that some unavoidably results from trying to provide the information necessary to ensure that consumers understand the claim in its proper context. FDA believes that the versions of the claims that it is adopting mandate less information, and are significantly less complex, than those proposed. However, manufacturers who are not satisfied with the model claims are free to develop their own versions of the claim, provided that those versions include all of the information required by the authorizing regulation.

65. One comment asserted that product-specific health claims, which emphasize the role of a specific product or brand of product in a diet-disease relationship already the subject of an agency regulation, should be allowed and even encouraged.

FDA disagrees with this comment. Section 403(r)(3)(B)(iii) of the act directs the agency to require that health claims enable the public to understand the information in the context of the total daily diet. FDA believes that a claim that refers specifically to the health benefits conferred by the consumption of a certain brand name of product would unduly emphasize the importance of that brand in the context of the daily diet. Also, such claims could imply that other brands of the same food, as well as other foods containing the substance, might not have the same effect on the disease or health-related condition and thus be misleading under section 403(a) of the act. Accordingly, the agency rejects this comment's recommendation.

66. A number of comments suggested that FDA should develop health claims about general food choices, rather than substances, and a disease or health-related condition. Other comments, however, cautioned that such an approach might create more consumer confusion than benefit.

As FDA pointed out in its response to comment 1 of this document, claims about the benefits of general classes of food such as fruits and vegetables that do not make an express or implied connection to any specific substances do not constitute health claims because the multiplicity of substances found in those foods renders the claim too general to satisfy the first basic element of a health claim (i.e., substance). However, where a claim about a general food choice is an implied claim for a substance or specific substances contained in the food and a disease or health-related condition, it would be subject to the health claims regime.

Development of information about general food choices and diseases or health-related conditions, to the extent it is not subject to section 403(r) of the act, is an activity authorized by the National Nutrition Monitoring and Related Research Act of 1990 (Ref. 32) which was enacted at about the same time as the 1990 amendments. In brief, the Nutrition Monitoring and Related Research Act authorizes the Secretary of the Department of Health and Human Services and the Secretary of the Department of Agriculture to establish dietary guidance by jointly publishing at least every 5 years a report entitled "Dietary Guidelines for Americans." Each such report is to contain nutritional and dietary information and guidelines for the general public which are based on the preponderance of the scientific and medical knowledge that is current at the time the report is prepared. The Secretaries are also authorized to review and approve any dietary guidance for the general population or identified population subgroup proposed to be issued by any Federal agency to assure that the guidance either is consistent with the "Dietary Guidelines for Americans," or that the guidance is based on medical or new scientific knowledge that is determined to be valid by the Secretaries.

The goals to be achieved by both the 1990 amendments and the Nutrition Monitoring and Related Research Act (7 U.S.C. 5341) are complementary in every respect. Where the 1990 amendments ensure the validity of health claims, the Nutrition Monitoring and Related Research Act ensures the validity of dietary guidance. In considering whether to authorize health claims, the agency will exercise great care to see that the claims that it authorizes are fully compatible with national dietary guidance.

B. Complete, Truthful, and Not Misleading

Proposed § 101.14(d)(2)(iii) stated that a health claim shall be complete, truthful, and not misleading. In keeping with these requirements, FDA asserted that where factors other than consumption of the substance bear on the claimed effect on a disease or health-related condition, such factors must be addressed in the claim.

67. One comment proposed that the word "complete" as used in proposed § 101.14(d)(2)(iii) is vague and would lead to confusion. It noted that each company in the food industry will be free to paraphrase FDA's model health claims and, since such paraphrasing necessarily implies different words and sentences, to the extent that a company's claim does not track the model exactly, such claims will not be "complete." The comment suggested that the word "complete" be deleted from the final regulation.

FDA disagrees that the word "complete" should be deleted from the regulation. The agency believes that it is imperative that consumers be informed of factors other than the consumption or nonconsumption of the substance that significantly bear on the claimed effect on a disease or a health-related condition. To this end, FDA will codify all such information in part 101, subpart E. FDA believes that the word "complete" is necessary in § 101.14(d)(2)(iii) to ensure that manufacturers understand that their health claims must include all such mandated information. This policy is consistent with section 201(n) of the act, which provides that an article's labeling may be misleading if it omits material facts.

68. One comment stated that dietary supplements should be required to balance their health claims by including warnings against any negative health effects that might result from their use. The comment also suggested that the labels of such products should declare the maximum amount of the dietary supplement that can be consumed without incurring risk of toxicity.

FDA disagrees. To be eligible for a health claim, a substance, if it is to be consumed at other than decreased dietary levels, is required to be a food or a food ingredient whose use at the levels necessary to justify the claim is safe and lawful under the applicable food safety provisions of the act. Thus, there is no reason to treat dietary supplements any differently than other food by requiring that they bear special warnings.

To avoid any misunderstanding as to the appropriate level of consumption in relation to the daily diet, the agency may require, in its authorizing regulation for a claim, that the claim state the level of consumption beyond which no additional benefit is likely to be gained. The agency notes as an example that the calcium/osteoporosis health claim includes the statement that "adequate calcium intake is important, but daily intakes above about 2,400 mg are not likely to provide any additional benefit."

If at some point in the future, the agency approves a health claim that has some safety concern to any subpopulation of consumers, the agency will, of course require that the claim include sufficient information to alert that subpopulation. For example, if FDA

ever approves a health claim for vitamin D, the claim would be required to inform consumers of the potential for an adverse effect from excess consumption.

C. Layout

Proposed § 101.14(d)(2)(iv) stated that all claims must appear in one place, in the same type size, without intervening material. FDA included in this provision an exception to allow a short reference statement to appear on the label, "See ———— for information about the relationship between ———— and ————," with the blanks filled in with references to the location of the labeling (other than the label) on which the full claim appears, the name of the substance, and the disease or health-related condition.

69. A number of comments suggested that proposed § 101.14(d)(2)(iv) be amended to allow the use of a front-panel reference to a full health claim appearing on the side or back panels. Many of these comments contended that a referral statement on the principal display panel would help make consumers aware of the full claim, which itself might be too long to appear on the principal panel. Some comments suggested that abbreviated forms of a health claim be allowed to serve as reference statements. One of these comments suggested that this approach would avoid overcrowding of the principal display panel, would place the health claims where they would be of greatest use to consumers, and would still provide conveniently located, detailed information to consumers.

FDA takes note of those comments on reference statements and abbreviated health claims. Some of the issues raised by these comments have been resolved with revisions made in all of the model health claims. For example, among the sample claims for sodium and hypertension in new § 101.74(e) is one that reads: "Diets low in sodium may reduce the risk of high blood pressure, a disease that is dependent upon many factors." Similarly short claims have been developed for other health claims. Since these abbreviated claims are not much different in length than a reference statement that would have been used on the principal display panel or elsewhere in labeling of a product, it is now possible to present the health claim in place of a reference statement. However, since the agency cannot provide assurance that future health claims will be crafted to be as short at the example given above, FDA has retained proposed § 101.14(d)(iv). The agency's responses to comments on reference statements and abbreviated claims follow.

FDA does not believe that it is appropriate to use abbreviated health claims as referral statements. Shortened health claims used as referral statements, even those as simple as "See side panel for information on how calcium may reduce the risk of osteoporosis," still constitute a health claim because they clearly characterize the relationship between a substance and a disease or health-related condition. Further, such a health claim is misleading because it does not include facts that are material in light of the representation that is made, and that are necessary to understand the claim in the context of the daily diet. For example, in the case of calcium and osteoporosis, the shortened claim does not reveal that regular exercise and a balanced diet are important to the maintenance of good bone health, and that a daily intake of calcium in excess of 2,400 mg is not likely to provide additional benefit for reducing the risk of osteoporosis.

Such situations are possible whenever the full health claim information appears in a location different from that of the reference statement and are especially likely to occur when a multiplicity of labeling is associated with a product. For example, a cereal manufacturer could place an abbreviated claim as a reference statement on the principal display panel of the cereal box and then bury the full claim on one of several paper inserts. In such a case, a consumer is unlikely to search through the inserts to find the full claim. A similar situation might arise were a grocer to display an abbreviated calcium-osteoporosis claim as a referral statement on a dairy case and then place the full claim on a billboard in a far corner of the store. A consumer is not likely to search through the store for the detailed health information.

In each of these examples, the consumer would be misled because he/she has received an incomplete health claim that does not disclose information on nondietary factors that may affect the nutrient-disease relationship and that does not allow the consumer to understand the claim in the context of the total daily diet. Case law clearly supports the agency's position that the mere presence of the full health claim elsewhere in the product labeling does not counteract the misleading nature of the abbreviated reference statements in such instances. See, e.g., *U.S.* v. *An Article of Food * * * "Manischewitz * * * Diet Thins,"* 377 F. Supp. 746, 749 (E.D.N.Y. 1974).

The referral statement provided in § 101.14(d)(2)(iv) does not constitute a health claim, as it does not characterize the relationship between a substance and a disease or health-related condition. The statement simply refers the consumer to a location where the complete health claim appears. A consumer who reads the referral statement without reading the full health claim may realize that there is some relationship between the nutrient and the disease. The nature of that relationship, however, is only presented in a context that is complete, truthful, and not misleading and that thus allows the consumer to fully understand and evaluate the claim. Thus, the consumer will not be misled by reading the provided referral statement. Accordingly, the referral statement provided in proposed § 101.14(d)(2)(iv) is the only one that should be used. As explained previously in this preamble (section I.D.5. of this document), the statement must appear in immediate proximity to any graphic material such as a symbol that constitutes an explicit or implied health claim.

70. A number of comments suggested that the complete health claim should be allowed only on the principal display panel unless the panel is too small to accommodate it.

FDA does not agree that health claims should be required to appear only on the principal display panel. The adoption of such a policy, for those labels that are physically large enough to contain the full health claim, could easily lead to overcrowding of some principal display panels and would eliminate their use on those that are not. Such a requirement would significantly undercut the congressional intent in providing for health claims in section 403(r) of the act. Therefore, FDA rejects this comment.

71. A number of comments asserted that the type size requirement proposed for health claims is not mandated by law. It was also argued that the requirement may make it impossible for manufacturers to include other truthful and nonmisleading information on the principal display panel.

FDA recognizes that the proposed type sizes are not mandated by law. The agency proposed this requirement because it was concerned that many consumers, when faced with a health claim printed in differing type sizes, might read only those portions of the claim that appear in larger type and thus would overlook the information printed in smaller type. However, FDA has reconsidered this issue and now believes that, as proposed, the provision is unnecessarily restrictive. Certainly consumers would not likely ignore portions of a health claim that are

printed in a reasonably related type size to the largest printed matter in the claim. FDA believes that any abusive use of type size could adequately be prevented under § 101.14(d)(2)(iii), which requires, in part, that a claim not be misleading. Accordingly, FDA has removed the requirement that a claim appear in the same type size. While the agency encourages manufacturers to observe the minimum type size required by § 101.2 for mandatory labeling information to ensure that the claims are easily legible, manufacturers who want to include a complete health claim on the principal display panel of a product may utilize whatever type size they feel is necessary to achieve this end.

72. One comment recommended that, in order to avoid the label space problems that would result from the appearance of lengthy bilingual claims, health claims on imported products should be allowed to appear in English without translations into the foreign languages that appear on the label. The comment asserted that competitive pressure will force U.S. importers to make label claims comparable to domestically produced products and cited the model health claim for calcium and osteoporosis in exemplifying the difficulty that would result from providing lengthy bilingual claims. Another comment from a foreign industry organization objected to permitting any health claims on food labels because multi-language labeling will be so burdensome that it will serve as a nontariff trade barrier.

FDA advises that the provisions of § 101.15(c)(2) require only that all mandatory labeling information be translated into any foreign languages that appear on any part of a product's labeling. Because the presence of a health claim on a food label is voluntary, manufacturers who place an English-language health claim on a multi-language label may choose whether to translate that claim into one, all, or none of the foreign languages appearing on the label.

D. Enables Public to Understand Significance of Claim in Context of Total Daily Diet

Proposed § 101.14(d)(2)(v) stated that a health claim must enable the public to comprehend the information provided and to understand the relative significance of such information in the context of a total daily diet.

73. Some comments asserted that the multiplicity of labeling requirements exceeds the statutory language of the 1990 amendments and stated there is no evidence in the legislative history to suggest that Congress intended label claims about nutrient/disease relationships to include the kinds of detailed information mentioned in the preamble. One of these comments stated that FDA is authorized under the amendments to require only that information that is necessary to prevent the health claim from being misleading.

Another comment disagreed with FDA's conclusion that section 403(r)(3)(B)(iii) of the act allowed "only those effects found to be substantiated" to be included in the health claim. The comment instead asserted that the requirements of the provision would be fulfilled if a health claim merely characterized the level of a nutrient vis-a-vis a disease, provided that there was significant scientific agreement that the intake of the nutrient at the level present in the food was beneficial in reducing the risk of the disease.

FDA disagrees with these comments. Section 403(r)(3)(B)(iii) of the act requires that a regulation that authorizes a claim require that the claim be stated in a manner that enables the public to comprehend the information in the claim and to understand the relationship of the substance to the disease, the significance of the substance in affecting the disease, and the significance of the information in the context of the total daily diet. Thus, a wide variety of factors may need to be addressed in the claim in order to fulfill these requirements, and the agency is not limited to requiring only that information that is necessary to prevent a claim from being misleading.

For example, the regulation authorizing a claim on the relationship between calcium and osteoporosis requires that the claim explain that adequate calcium intake during adolescence and early adulthood appears to have a positive effect on bone health, and that optimizing peak bone mass during that period may reduce the risk of osteoporotic fracture in old age (see new§ 101.72(d)(3)). Additionally, the regulation requires that claims point out that adequate calcium intake be accompanied with exercise and the maintenance of a balanced diet. The claim must also identify factors such as the age range within which women can expect to achieve the greatest effect for decreasing the risk of developing osteoporosis in later life (see new § 101.72(d)(2)). These are considered to be facts essential for consumers to understand the conditions and circumstances under which the claimed effect of calcium on the risk of osteoporosis is more likely to be obtained.

Accordingly, if FDA were to permit a health claim that simply characterized the level of a nutrient vis-a-vis a disease or health-related condition, the agency would not meet the statutory requirements of section 403(r)(3)(B)(iii) of the act. Therefore, FDA rejects the comments.

74. Some comments stated that the model health claims were themselves misleading in that the identification of certain high-risk groups in a claim might easily lead consumers in other groups to believe that the information presented in the claim does not apply to them, when in fact it may (for example, osteoporosis affects some men as well as women).

The model claims that are targeted to specific subpopulations have been carefully worded to encompass all of the affected subpopulations. The agency, therefore, sees no potential for a consumer who is in a group that is at increased risk of a disease that is discussed in a health claim to be misled by the claim into believing that he/she is not at an increased risk of the disease. The agency addresses concerns about specific model health claims in the preambles to the specific regulations authorizing those claims.

75. Other comments asserted that model health claims should emphasize the importance of good nutrition habits to all consumers. One also recommended that FDA require a statement about the need to seek medical advice for treating the related disease as part of the health claim.

FDA does not agree that it is appropriate to require that all health claims emphasize the importance of good nutrition to all consumers. In many cases, a health claim may be targeted toward a specific subpopulation. The inclusion of a statement directed at the general U.S. population could lead some consumers who are not targets of the claim to mistakenly believe that the entire health claim has relevance to them. For example, a calcium-osteoporosis claim targeted toward teenage women that bears a statement concerning the importance of good nutrition to the general population could mislead some middle-age men with no family history of osteoporosis to believe that the claim was also targeted toward them.

Also, FDA does not believe that it is appropriate for health claims to bear statements concerning the need to seek medical advice for treating the disease or health-related condition mentioned in a claim. The agency is concerned that the appearance of a statement concerning the treatment of a disease on the label of a food could mislead some consumers to believe that the food possesses therapeutic value for an

existing disease or health-related condition. Further, such an interpretation could encourage some consumers who suffer from the disease or condition to attempt "home remedies" by consuming more of the product and, ironically, temporarily or even permanently foregoing the medical attention that they need.

E. Presence of "Low" Level of Nutrient to be Consumed at Decreased Dietary Levels; Presence of "High" Level of Nutrient to be Consumed at Other Than Decreased Dietary Levels

Proposed § 101.14(d)(2)(vi) stated that to bear a claim about the benefits of consuming a substance at reduced dietary levels, a food must be sufficiently low in that substance to meet the definition of the term "low" if the term has been defined for that substance, or if the term has not been defined, to meet the level set in the regulation authorizing the claim. Proposed § 101.14(d)(2)(vii) stated that to bear a claim about consuming a substance at other than decreased dietary levels, a food must be sufficiently high in that substance to meet the definition of "high" if the term has been defined for that substance, or if the term has not been defined, to meet the level set in the regulation authorizing the claim.

With the decision in section II.B of this document to revise the definition of "substance" in proposed § 101.14(a)(2) to include a specific food as well as a component of food, the requirements of proposed § 101.14(d)(2)(vii) (i.e., the requirements for "high") must be revised as they apply to a health claim for a specific food. Where a health claim for a specific food (e.g., garlic, rice bran) is established by the agency, it is presumed that the claim will deal with either inclusion of the food in the diet or increased dietary intake to effect the benefit that is the object of the claim. The agency does not envision authorizing a health claim for a specific food based on decreased intake of that food because, where moderation in or a decrease in daily intake is at issue, that action is directed toward food components rather than whole foods (e.g., "choose a diet low in fat, saturated fat, and cholesterol;" "use sodium only in moderation").

Accordingly, FDA has revised proposed § 101.14(d)(2)(vii) to state that, where no definition for "high" has been established, that is where the claim pertains to a whole food or to the food's use as an ingredient in other foods, the claim must specify the daily dietary intake necessary to achieve the claimed effect as established in the regulation authorizing the claim.

76. Most comments concurred with the proposal to allow a health claim only when a food contains the claimed substance in an amount that meets the criterion for either a "high" or "low" level of that substance. However, some comments qualified their concurrence by saying that they did not agree with the definitions for "high" and "low." One comment stated that, absent a definitive showing that health claims would be misleading on foods that do not meet the "high" or "low" definitions, FDA's approach cannot be considered narrowly tailored to directly advance the government's interest in providing important diet and health information to consumers. Unless deception could be proved, the comment urged FDA to eliminate the requirements linking health claims to "high" and "low" definitions for nutrient content of foods.

The agency has considered these comments and concludes that it is appropriate to retain the requirements in proposed§§ 101.14(d)(2)(vi) and (d)(2)(vii) linking health claims to "high" and "low" definitions for nutrient content of foods. The definitions for "low" and "high" levels of a substance (nutrient) have been developed specifically to assist consumers in maintaining healthy dietary practices (see section 403(r)(2) of the act). The same basis underlies the purpose for health claims. This is evident from the House of Representatives report on the 1990 amendments (Ref. 1):

> The Surgeon General has advised Americans that diets low in fats, low in salt and high in fiber can reduce the risk of chronic diseases such as cancer and heart disease. Health claims supported by a significant scientific agreement can reinforce the Surgeon General'[s] recommendations and help Americans to maintain a balanced and healthful diet. Similarly, statements regarding the level of these nutrients in foods will assist Americans in following the Surgeon General's guidelines.

Accordingly, a requirement with respect to the level in a food of a substance that is the subject of a health claim is consistent with the intent of the 1990 amendments. The definitions of "high" and "low" are addressed by FDA in the rule on nutrient content claims published elsewhere in this issue of the **Federal Register**.

77. One comment urged FDA to modify the proposed requirement that would permit a health claim on a product for which a nutrient (specifically sodium) is assessed only on the basis of the reference amount customarily consumed (as defined in the final rule on serving size published elsewhere in this issue of the **Federal Register**). The comment suggested that the product should additionally comply on the basis of the total amount of the nutrient in the actual package if the package contains less than 200 percent of the reference amount customarily consumed.

This comment misinterpreted FDA's proposal. In the proposal on serving sizes (56 FR 60394), FDA proposed that both the reference amount customarily consumed (hereinafter referred to as the reference amount) and the label serving size be used to determine whether a product met the criteria for both nutrient content and health claims. The agency solicited comment on another approach that is based solely on the reference amount and that would require a disclaimer where, for example, a reference amount of a product would qualify for a sodium claim, but a single-serving container with 150 percent of the reference amount would not.

As discussed in detail in the preamble to the final rule on serving sizes published elsewhere in this issue of the **Federal Register**, the agency has considered the comments on this issue, along with the advantages and disadvantages of both options, and acknowledges that nutrient content claims should reflect, and health claims should be based on, the reference amount customarily consumed. The agency has concluded that problems created when the amount of the substance in the labeled serving size would not qualify for a claim are resolved by requiring a disclaimer that makes clear the basis for the claim. This disclosure is necessary to ensure that the consumer is not misled. On this basis, the agency is rejecting the recommendation made by this comment.

The agency has reflected this determination with respect to claims in new § 101.12(g) of the final rule on serving sizes, published elsewhere in this issue of the **Federal Register**, which has been revised in response to comments to that proposal to state, in part:

> The reference amount [i.e., the reference amount customarily consumed] set forth in paragraphs (b) through (f) of this section shall be used in determining whether a product meets the criteria for nutrient content claims, such as "low calorie," and for health claims. If the serving size declared on the product label differs from the reference amount, and the product meets the criteria for the claim only on the basis of the reference amount, the claim shall be followed by a statement that sets forth the basis on which the claim is made. That statement shall include the reference amount as it appears in § 101.12(b)

followed, in parenthesis, by the amount in common household measure if the reference amount is expressed in measures other than common household measures (e.g., for a beverage, "Very low sodium, 35 mg or less per 240 mL (8 fl. oz)").

That declaration is necessary because in containers of this type, consumers customarily consume more than the reference amount. The declaration is necessary to ensure that the claim is not misleading. The criteria for health claims referenced in proposed § 101.12(g) are the qualifying criteria contained in proposed §§ 101.14(d)(2)(vi) and (d)(2)(vii). Therefore, to reflect the modification that has been made in § 101.12(g) that a health claim can be made on a product when the product meets the criteria of proposed §§ 101.14(d)(2)(vi) or (d)(2)(vii) only on the basis of the reference amount customarily consumed, new § 101.14(d)(2)(vii)(A) has been added to state:

> Where the food that bears the claim meets the requirements of paragraphs (d)(2)(vi) or (d)(2)(vii) of this section based on its reference amount customarily consumed, and the labeled serving size differs from that amount, the claim shall be followed by a statement explaining that the claim is based on the reference amount rather than the labeled serving size (e.g., "Diets low in salt and sodium may help lower blood pressure in many people. A serving of ———— ounces of this product conforms to such diets.").

F. Requirements for Restaurants

1. Health claims on restaurant foods

FDA received many comments regarding the proposed health claims criteria as they would apply to restaurant foods and to foods sold in other establishements in which food that is ready for human consumption is sold (e.g., institutional food service, delicatessens, catering). In this discussion, such foods will be referred to as "restaurant foods," firms selling such foods will be referred to as "restaurants," and responsible individuals in these firms will be referred to as "restaurateurs." However, the concepts and policies discussed are intended to apply broadly to the foods covered by section 403(q)(5)(A)(i) and (q)(5)(A)(ii) of the act. Issues with respect to menus are dicussed separately below.

78. Many comments objected that the proposed health claim provisions should not apply to restaurant foods and foods sold in other establishments in which food that is ready for human consumption is sold. These comments asserted that Congress did not mandate the application of the proposed health claim regulations to restaurant foods. A number of comments observed that section 403(q)(5)(A)(i) of the act exempts restaurant foods from mandatory nutrition labeling requirements, and that sections 403(r)(2)(A)(iii) and (r)(2)(A)(iv) exempt them from the restrictions placed on claims related to cholesterol, fat, and fiber content. The comments further noted that the 1990 amendments are silent with respect to the regulation of health claims made in connection with restaurant foods, and that, at a minimum, FDA is not required to regulate restaurant foods. Other comments maintained that even if the agency does believe that restaurants must be subject to health claims regulations, FDA is not obligated to regulate these foods in an identical manner to that proposed for packaged foods.

However, many other comments disagreed. Some of these comments maintained that because the 1990 amendments contain no specific exemptions for health claims in restaurants, Congress intended for restaurants to be fully subject to the health claim regulations. Other comments argued that restaurant food plays too great a role in the American diet not to have been covered by the 1990 amendments. One comment pointed out that a large percentage of the money spent for food by Americans is spent away from home in restaurants. Several comments stated that requiring restaurants to comply with all of the health claims regulations where they choose to make health claims would best support the philosophy of an "even playing field" between restaurateurs and other food vendors. Others expressed concern that the preemption clause of the 1990 amendments could prohibit state and local authorities from enacting regulations concerning health claims made on restaurant foods if FDA fails to do so. One consumer comment proposed that FDA ban restaurants from making any health claims for any of their products, rather than exempting them from the health claim regulations.

FDA believes that the provisions of the 1990 amendments pertaining to health claims clearly encompass restaurant food wherever a health claim is made (except, for the reasons discussed below, when the claim is made on a menu). FDA disagrees with comments that asserted that the absence of specific exemptions for restaurant food from the health claims provisions in these amendments conveys flexibility to the agency to exempt such food from § 101.14. The House Report (Ref. 1) states that "under sections 403(r)(1)(B) and 403(r)(3) of the act, restaurants and similar food service establishments would have to comply with the bill in order to make a disease claim concerning a food sold in such establishment." In view of this explicit statement of congressional intent on this matter and the presence of specific exemptions for restaurant food pertaining to other provisions of the 1990 amendments where Congress wanted different regulatory treatment for restaurant food, the absence of a restaurant food exemption pertaining to health claims can only mean that Congress intended for restaurants to be subject to health claim regulations. Because of the congressional intent that restaurants be subject to the health claim regulations, FDA disagrees with assertions that the agency should not permit health claims on restaurant food.

However, FDA agrees that it is not legally required to regulate claims on restaurant foods in a manner identical to that for packaged foods. Nevertheless, it is only logical that if claims on food are to be useful for consumers, the criteria for those claims must be consistent. Therefore, the agency has determined that additional flexibility is needed to facilitate the helpful provision of health claims on restaurant foods, but that there must be assurance that the claims being made are indeed valid. The agency's responses to the following comments discuss how FDA intends to achieve this degree of flexibility with appropriate assurance of validity.

79. Many comments argued that all health claims provisions affecting packaged food should also apply to restaurant food. Several comments stated that the regulation of restaurant foods would be practical because many of the menu items are centrally manufactured and are required to conform to system-wide composition and quality standards. One comment asserted that many restaurant chains, especially the larger ones, already have access to nutrition information about their products. Another comment stated that private services that determine the level of various nutrients in foods are readily accessible to restaurants. A comment from an organization representing the nation's state, local, and Federal food regulatory officials asserted that the proposed regulations would not place an additional burden on restaurants seeking compliance with the health claim requirements, as most state laws already require that foods be labeled in compliance with all applicable laws and regulations and do not differentiate between labeling at the wholesale or manufacturing level and the retail level. The comment cited the model regulations developed jointly

between FDA and the Association of Food and Drug Officials (Rules of Food Service Sanitation and the Retail Food Store Sanitation Code) as an example. Other comments argued that health claims are misleading without nutrition labeling information. Some comments suggested that restaurants be required to at least provide an abbreviated nutrition statement, consisting of a disclosure of the amount of calories, fat, and sodium as well as of all nutrients relevant to the health claim.

However, many comments confirmed that restaurant food differs in a number of significant respects from other types of food that is mass-produced and packaged and maintained that the differences make it impracticable for restaurants to conform to some of the health claims provisions that were proposed. The comments advised that the provisions at issue are those pertaining to qualifying levels (e.g., the "low" or "high" levels of the substance, as appropriate) and the "disqualifying nutrient levels," as well as nutrition labeling. The comments asserted that the cost of providing nutrient content information would be unreasonable for each of these provisions. Some of these comments explained that restaurants experience significant variations in the foods they serve because of variations in the manner of preparation, varying ingredients, consumer preferences, varying serving sizes, and the lack of central control over food preparation in many restaurants. Because of this wide variation, frequent nutrient analyses would have to be performed to determine nutrient content, so that restaurants may conform to these provisions. The comments advised that these analyses could become very burdensome, and that the cumulative costs of these analyses could prevent establishments from making health claims, prevent them from making frequent changes in the dishes they offer, or force them to limit the options that consumers have in ordering a food. Further, the comments advised that small businesses would be especially burdened by such cumulative costs.

Even in "standard" items in multi-unit operations, the comments asserted, there is inherent variation. The comments advised that such variation is present in items such as daily specials, test products, local optional items, promotional items, and all items in restaurants offered for limited periods of time. A number of comments objected to the application of the proposed health claim regulations to traditional ethnic restaurants and similar small businesses on the grounds that it is extremely difficult to modify many of their foods to the degree necessary to meet the various provisions of the health claim proposals.

In addition, some comments pointed out that the proposal requires that qualifying and disqualifying levels be met per reference amount, per serving, and per 100 g. This aspect of the proposed definition, the comments maintained, wreaks havoc when applied to restaurant foods. Comments advised that restaurant foods that conform to the proposed qualifying and disqualifying levels in terms of reference amounts and 100 g are nonetheless ineligible to use health claims because their larger serving size results in the food failing to conform to the disqualifying nutrient levels. A number of comments suggested that restaurant food claims be judged on a per 100 g basis consistent with FDA's meal proposal, since most consumers view restaurant foods as a "meal."

Given that almost half of the American food dollar is spent on food consumed away from home, and that perhaps as much as 30 percent of the American diet is composed of foods prepared in food service operations, FDA believes that, from an overall public health perspective, this important segment of the diet can not be ignored. Further, FDA believes that dietary information, including health claims, provided to consumers at point of purchase in restaurants may be useful in helping Americans in maintaining healthy dietary practices. FDA wants to encourage the provision of such information. However, FDA firmly believes that consumers expect health claims made at point of purchase to be truthful and not misleading.

FDA advises that not all claims made for restaurant foods are necessarily the type of claims that are covered by the 1990 amendments. For the sake of clarification, the agency offers the following observations. Because of the importance of context, a restaurant may be able to use symbols next to the listing of an item where the symbols are clearly explained in terms that would not subject the claim to the 1990 amendments. Thus, restaurant labeling may use symbols or make reference to the criteria of a health professional organization and explain that the entree or meal is consistent with the general dietary guidelines of that group and not be subject to the 1990 amendments. For example, use of a heart symbol with reference to a note that explains that this entree is consistent with the dietary guidelines of the American Heart Association will be considered dietary guidance, and not a health claim subject to section 403(r) of the act. If the restaurateur went on to link the claim with levels of substances in the food, however, it would subject the food and the claims to the health claims regime (see discussion above about implied health claims).

When a restaurant makes explicit or implied reference to a substance and directly or indirectly links levels of that substance in the food to an effect on the risk of a disease or health-related condition (i.e., when both basic elements of a health claim are present) on a sign or placard, it must comply with the health claims regime.

How the restaurant demonstrates compliance with that regime is a difficult matter. FDA recognizes that, as detailed in the comments, there are variations in the nutrient values for restaurant foods. Some of these variations are not unique to restaurants. Manufacturers of packaged foods also have to deal with differences in nutrient levels that result from seasonal, regional, and supplier variations. FDA has been able to develop workable criteria that take into account these variations. However, the agency acknowledges that there are variations unique to restaurant foods (e.g., methods of preparation). Moreover, FDA recognizes that there are difficult questions, as demonstrated by the comments, as to how exactly to analyze restaurant foods in a reasonable and cost effective manner.

While there are difficulties associated with restaurant foods, FDA concludes that the difficulties are not so great as to preclude restaurants from making health claims or to prevent the agency from being able to assure consumers that the health claims that are made for restaurant foods are valid. Because of the nature of the difficulties, however, FDA is providing in § 101.14(d)(2)(vii)(B) that a restaurant food may bear a health claim if the restaurateur has a reasonable basis on which to believe that the food that bears the claim meets the regulations for the claim that FDA has established under section 403(r) of the act, and that basis is provided upon request. The difficulties and costs outlined in the comments would make it unfair to require that restaurateur determine whether their food qualifies for a claim in the same manner that a manufacturer of a packaged food makes this determination. By requiring that the restaurateur have a reasonable basis to believe that the food qualifies, the restaurateur, is provided with a readily achievable way to make claims for his or her food, and the consumer is provided with a reasonable assurance that the claim is valid. Thus, if a

restaurateur labels a vegetarian main dish or meal as "heart healthy," he must have a reasonable basis for believing that the product contains less than the disqualifying level for sodium and meets the "low" definitions for fat, saturated fat, and cholesterol.

The reasonable basis can be provided in a number of ways. The restaurateur can show, for example, that FDA's guidelines on nutrition labeling of fruits and vegetables show that meal or main dish is "low fat," "low saturated fat," "low cholesterol," and does not contain a disqualifying level of sodium, and that the method of cooking the meal or main dish would not add fat or any disqualifying nutrient. In addition, the restaurateur could show that he or she used a reliable cookbook that gave values for fat, saturated fat, sodium, and cholesterol in the finished food that met FDA's requirements for making the health claim. Certainly other methods are possible. If a restaurateur uses recognized data bases for raw and processed foods to compute nutrient levels in the foods or meals and then does not use methods of preparation that violate the appropriate use of data bases (e.g., uncontrolled addition of ingredients, inappropriate substitutions of ingredients), FDA will consider this use to be a reasonable basis for believing that the food meets the qualifying and disqualifying levels. Upon demand, the restaurateur will be expected to present to appropriate regulatory officials information on the pertinent nutrient levels in the foods and the basis on which these levels were determined. A determination will then be made as to whether the basis of calculation reasonably supports the restaurateur's use of a permitted health claim. FDA believes that the reasonable basis approach will make it practicable for all restaurants, including those that are very small businesses, to provide consumers with better information on more healthful dietary choices for the foods that they offer for sale.

Further, this reasonable basis approach for making a health claim will provide regulatory officials, especially State and local authorities, with an effective standard for verifying that claims made for restaurant-type foods are truthful and not misleading and in accordance with FDA regulations. While health claims used in restaurants are under FDA's jurisdiction, the agency does not have resources to adequately enforce its regulations in restaurants. State and local authorities have traditionally carried out this responsibility. In addition, section 4 of the 1990 amendments provides that State and local authorities may enforce section 403(r) of the act in Federal court.

While restaurants, and particularly small restaurants, have nominally been subject to FDA's existing nutrition labeling regulation (see § 101.10), they have, as a practical matter, not been required to comply with these regulations or with State or local regulations that focused on the nutrient content of the food. Thus, the efforts that will be necessary on the part of restaurants to show that they have a reasonable basis to believe that their food complies with the health claims requirements will be significant. These efforts will place particularly great demands on the resources of the small business segment of the industry, that is, restaurant firms that have ten or less individual restaurant establishments (Ref. 37). FDA will refer to this segment of the industry as "small restaurants."

Small restaurants generally do not have the established nutrition support component that larger restaurant chains have. Thus, it will be more difficult for small restaurants to determine how to adapt health claims information to their food preparation methods. In addition, it is likely that they will not be as aware of available information sources, like nutrient content data bases, as large chains. Moreover, because of resource limitations, a small restaurant is not as likely as a large restaurant chain to be familiar with Federal requirements. Thus, small restaurants will have to become familiar with not only FDA's requirements, but with available FDA information, like the nutrient content information that FDA published in conjunction with its regulation on the voluntary labeling of raw fruits and vegetables (56 FR 60880, November 27, 1991).

Because of the great initial demands that small restaurants will find if they wish to make claims, FDA has decided that they should be given additional time to come into compliance with these regulations. Without additional time for the reasons discussed above, small restaurants will be place at a disadvantage with respect to their ability to make claims. As a result, they may decide not to even attempt to provide useful nutrition information to consumers about the foods they serve. To provide for equitable implementation of these requirements for small restaurants, FDA has decided to not make part 101 effective with respect to such establishments until May 1994.

While the statute will be in effect during that period, FDA will not enforce the statute's health claim requirements in small restaurants until the regulations are effective. Although state action is not preempted under section 403A(a)(5) of the act until Federal regulations are effective, the agency expects that states will refrain from enforcing any health claim requirements in small restaurants until the Federal regulations are effective for those restaurants.

FDA believes that this action is fully consistent with the 1990 amendments and with the act. The 1990 amendments impose no date by which the agency's regulations must be effective, only when they must be promulgated (see sections 3 and 10 of the 1990 amendments). Moreover, FDA believes that this action will facilitate effective enforcement of the act. FDA believes that the agency's and State resources can best be used during this initial period in educating small restaurants about the requirements of the law and by developing a better understanding of the unique practical circumstances of small restaurants in complying with health claims labeling requirements. Moreover, during this period, there will be an opportunity for interested persons to develop new data bases that will help facilitate the provision of nutrition information on foods sold in restaurants and particularly in small restaurants.

As an additional measure of flexibility, which will especially benefit small restaurants, it was decided not to include claims on menus within the coverage of these regulations. FDA has considerable discretion in regulating health claims in restaurants. As the comment's have indicated, there are unique problems and concerns associated with regulating such claims. The 1990 amendments do not specify precisely how such claims are to be regulated. These regulations will apply to health claims made in restaurants except on menus. The agency's efforts will focus on signs, placards, and posters, which are increasingly used in fast food and other restaurants to bring nutrition information and claims about food to consumer's particular attention. The comments pointed out that menus are subject to frequent, even daily, change. This additional measure of flexibility for menus will help assure that restaurants, especially small restaurants, will not be deterred by the 1990 amendments from providing useful nutrition-related information to their customers. State's remain free, however, to ensure under their own consumer protection laws that menus do not provide false or misleading information.

Although it has arrived at an approach that will provide for health claims on restaurant foods, FDA does not consider the problem of restaurant

food to be solved. It is possible that there are other health claim criteria that are more appropriate for restaurant foods than those that FDA has developed based largely on packaged foods. Also, it may be that consumers have completely different expectations for, and understanding of, restaurant foods as compared to packaged foods. If so, different criteria for use of health claims in restaurants may be appropriate. However, at this time, the agency simply does not have the data or knowledge on which to base such determinations. FDA is working, and will continue to work, with the restaurant industry to determine how health claims are used on restaurant foods, and whether such claims are appropriate. For example, with FDA's cooperation, the National Restaurant Association has undertaken a survey of industry use of nutrition information and of consumer knowledge, practices, expectations, and understanding of various terms and symbols in restaurants. FDA is open to petitions for different criteria for health claims for restaurant foods, and if data warrant, the agency will consider establishing regulations specifically for restaurant foods.

FDA also recognizes that there are a number of significant issues concerning the adequacy of currently existing data bases for use to compute nutrient levels in restaurant meals. However, the agency is working, and will continue to work, with the restaurant industry to assess the adequacy of these data bases and to encourage the development of additional or newer data where those data bases are found to be lacking.

In developing more specific policies, FDA will also consider whether restaurant foods should be afforded greater latitude in the compliance criteria than the criteria that are currently applied to nutrient variations in processed foods. FDA regulations state that, for naturally occurring vitamins, minerals, and protein, the nutrient content must be at least 80 percent of the value declared and for calories, carbohydrate, fat, and sodium, the level must not exceed the declared value by more than 20 percent. The agency recognizes that all data bases have inherent variabilities, and that a computed nutrient level for a food with several ingredients may have an accumulated variability that exceeds the agency's criteria for packaged foods. FDA is concerned about the accuracy of nutrient level estimations, but pending the development of better data, the agency will accept, as a reasonable basis, claims verification based on nutrient levels from recognized nutrient data bases, without regard to the computed variability or to differences between the computed nutrient levels and levels determined by laboratory analyses. The agency is open to comments and suggestions on how nutrient variability issues should be addressed for restaurant foods and will continue to work with the industry on this issue.

80. Some comments cautioned that any adopted health claims provisions applied to restaurants must be flexible in format and content. These comments asserted that the distinct differences between the delivery systems of restaurant foods and packaged retail products must be factored into the regulations if they are to apply to restaurant foods, as most consumers select and purchase their food before ever seeing it or its container. Other comments asserted that the impracticality of compliance with the current inflexible health claims regulations would tempt restaurant operators to simply choose not to promote healthful menu alternatives.

FDA does not agree that firms should be given special flexibility concerning the content of health claims that appear on restaurant food. FDA believes that section 403(r)(1)(B) and (r)(3)(b)(iii) of the act require that a health claim be complete and consistent with the authorizing regulation. Specific health claims regulations in part 101, subpart E set forth certain mandatory aspects of permitted health claims. Where any mandatory aspect of a health claim is absent, the claim will be misleading, and the agency cannot sanction such a situation.

With respect to format, FDA believes that there is already ample flexibility in the rules that it is adopting. For example, new § 101.14(d)(2)(iv) permits full health claims to appear on any part of a food's labeling, including a sign or a placard. Accordingly, labeling listing 20 items, 3 of which qualify for the fat-cardiovascular disease claim, could carry the full health claim next to each of the 3 qualifying items. Alternately, it could list the names of the three items in a distinct area, such as a box or section, and print the full health claim once within that area.

New § 101.14(d)(2)(iv) also provides for the use of a short referral statement that directs the consumers' attention to another part of the food's label or labeling where the full health claim appears. Therefore, in the example above, the message "See _____ for details concerning the relationship between fat and cancer" could appear next to each of the items or in the box, with the full health claim printed only once in the label or in the labeling location identified in the blank. For example, the labeling could be in the form of placards placed in full view of the consumer, flyers made available to the public, and other such items. The agency cautions, however, that the referral statement must clearly be associated only with the item or items that qualify for the health claim, and that the location of the full health claim must not be such that it is likely to be associated with a product that does not qualify for the claim.

2. Nutrition labeling on restaurant foods making health claims

81. Many comments asserted that the cost of providing nutrient content information for restaurant foods making health claims would be unreasonable. Some comments that opposed any form of mandatory labeling requirements offered ways in which FDA could minimize the financial burden on restaurants, if any such regulations were in fact adopted. Many of these comments proposed that only fixed items should be required to bear nutrition labeling, thus exempting items such as daily specials, test products, local optional items, promotional items, and all items in restaurants for limited periods of time. Some comments asserted that FDA should permit the use of various data bases, including computer reference bases, for the determination of a food's nutrient content. Other comments suggested that only chains should be required to furnish nutrition labeling for their foods. Other comments suggested that any restaurant with profits of below $50,000 be exempted from any nutrition labeling requirements. However, comments from larger restaurant chains argued that any nutrition labeling requirements should be applied equitably to the restaurant industry as a whole, because a selective application of the regulations could place major chains at an economic disadvantage.

FDA finds nothing in the comments to persuade the agency to adopt a position different from that stated in the general requirements proposal (56 FR 60553). The agency continues to believe that it has the authority to issue regulations requiring restaurants that make health claims to adhere to the requirements for such claims including nutrition labeling. Full nutrition labeling provides the consumer with a way of evaluating a claim within the nutrient context of the food or meal and, therefore, is advantageous in allowing more informed comparisons. However, in the general principles proposal for nutrient content claims (56 FR 60427),

the agency recognized the difficulty of providing nutrition labeling for restaurant foods and asked for comment. The comments have persuaded the agency that, at this time, a requirement for full nutrition labeling could be a significant barrier to the transfer of information about favorable health-related characteristics of restaurant foods. Therefore, FDA is not requiring that full nutrition labeling be provided when a health claim is made for restaurant foods. The agency is adopting a somewhat different approach to the provision of nutrient information to the consumer, as explained below.

FDA believes that consumers should have information about the nutrient content of restaurant foods on which health claims are based. The agency has therefore established alternative nutrition labeling provisions for restaurant food in new § 101.14(d)(3) providing for such information in lieu of full nutrition labeling. For example, if a meal is characterized as being "heart healthy," the restaurateur should be able to provide consumers with information about the level of the nutrients that provide the basis for the claim. Therefore, the agency will require that if a restaurateur makes a health claim for a meal, he or she must be prepared to advise the consumer about the information that provides the reasonable basis for believing that the food complies with FDA's requirements for the claim (e.g., nutrient levels from data bases, cookbooks, or analyses). For the interim, the agency will consider that the provision of this limited amount of information to consumers will serve as the functional equivalent of nutrition labeling.

82. Many comments asserted that if restaurants are required to provide nutrition labeling, they should be afforded significant flexibility in determining where to present the required nutrient information. Some comments pointed out that restaurant food frequently is not packaged, and that, when it is packaged, the packaging is frequently too small to physically accommodate nutrition information. Other comments stated that much of the labeling used in restaurants is too small to physically accommodate nutrition information for all of the products which could potentially bear health claims. Some suggested that flyers, leaflets, and other printed handouts are acceptable places for such information to appear. Others suggested that all such information should be allowed to appear in a fixed location, such as in a wall display. Others suggested that tray liners be allowed to provide the nutrition information in fast food restaurants.

FDA agrees that restaurants do need significant flexibility in determining where to present the required nutrient information. Accordingly, the agency has revised the nutrition labeling provision in new § 101.14(d)(3) to provide that restaurants may provide nutrition labeling information through conformance with the provisions of § 101.9 or § 101.10, as appropriate. (In response to the DS Act, FDA has removed the reference to § 101.36 in this regulation.) As explained in the next comment, § 101.10 has been revised to convey considerable flexibility for nutrition labeling for restaurants.

83. Many comments contended that in view of the above mentioned problems outlined in the foregoing comments, any regulations regarding health claims on restaurant foods should be promulgated under a separate rulemaking more tailored to the unique nature of the restaurant industry's needs. A number of comments asserted that existing nutrition labeling provisions pertaining to restaurants in § 101.10 are outdated by the application of the proposed health claim regulations to restaurant foods and suggested that those provisions be revoked or modified accordingly.

FDA has determined that § 101.10 should not be deleted. Rather this section is being revised to reflect the agency's determinations with respect to the need for a reasonable basis for believing that the food complies with the qualifying and disqualifying levels and with respect to the provision of information to the consumer. The revision of new § 101.10 has been addressed in the document concerning nutrient content claims that appears elsewhere in this issue of the Federal Register.

3. Other restaurant issues

84. One comment suggested that FDA develop educational materials that explain the obligations of restaurateurs relevant to health claims, and that FDA offer alternative, nonmisleading ways in which restaurants might communicate health-related information. The comment noted that the 1990 amendments called for FDA to educate the public about the regulations adopted under them.

Section 2(c) of the 1990 amendments directs the Secretary to carry out activities to educate consumers about the availability of nutrition information in the label or labeling of food and the importance of that information in maintaining healthy dietary practices. While the language of the act does not specifically direct FDA to develop educational materials for industry segments, the agency intends to work with industry, particularly trade associations and small restaurants, so that all parties (e.g., consumers, industry, and State/local regulators) understand the regulations and their obligations and rights under them. Further, FDA believes that the preamble to this document clearly defines those obligations and rights and thus should give the restaurant industry much of the guidance it needs. Where an issue is not resolved in the preamble to the full understanding of a restaurateur, the agency invites correspondence on the specific matters that are unclear.

VI. Prohibited Health Claims

A. Claims not Authorized by FDA

The provisions of new § 101.14(e)(1) and (e)(2) prohibit on a food label or in labeling any claim that expressly or by implication characterizes the relationship of any substance to a disease or health-related condition unless: (1) The claim is a health claim specifically provided for in part 101, subpart E; and (2) the claim conforms to all general provisions of new § 101.14 as well as to all specific provisions in the appropriate section of part 101, subpart E. These provisions embody the statutory restriction in section 403(r)(1)(B) of the act that directs that a food shall be deemed misbranded if a health claim is made in its label or labeling unless the claim is made in accordance with section 403(r)(3), which make such claims subject to the requirements adopted by the Secretary (and FDA, by delegation) by regulation. (Section 403(r)(1)(B) of the act also references section 403(r)(5)(D). However, action on that section is deferred based on the moratorium established by the DS Act).

85. Numerous comments voiced support for or opposition to the proposal to prohibit unauthorized health claims.

FDA has adopted new § 101.14(e)(1) and (e)(2) as proposed because they are explicitly required under section 403(r)(1)(B) and (r)(3) of the act. Because these regulations respond directly to the language of the act, FDA is constrained to adopt them.

B. Disqualifying Levels Exceeded

New § 101.14(e)(3) requires that none of the disqualifying levels identified in new § 101.14(a)(5) be exceeded in a food that bears a health claim, unless specific alternative levels have been established for the substance in part 101, subpart E, or unless FDA has by regulation

permitted such a claim based on a finding that such a claim will assist consumers in maintaining healthy dietary practices. If FDA makes such an exception, the label of the food will have to bear a statement in immediate proximity to the claim that refers the consumer to the nutrition label for information about the nutrient that exceeds the disqualifying level. This statement must be made in a manner that complies with proposed § 101.13(h).

FDA received numerous comments on its proposed disqualifying levels. Some comments voiced unsubstantiated support or disapproval for the proposals, while others offered substantive arguments for their positions. These comments are discussed in section II.G. of this document (see comments 23 through 42 of this document).

C. Inappropriate Levels of Other Substances

New § 101.14(e)(4) will prohibit claims for any food where a substance, other than one for which a disqualifying nutrient level is established, is present at an inappropriate level as determined in the specific provision authorizing the claim in part 101, subpart E. In the preamble to the proposed regulations, the agency explained that this provision will prevent health claims from appearing on foods that contain substances other than the substance that is the subject of the claim if any of those other substances, although not harmful in their own right, could interfere with the claimed effect on the risk of disease. For example, foods containing phosphorus in equal or greater proportion to calcium would not be eligible to bear the calcium-osteoporosis health claim, because diets high in phosphorus and relatively low in calcium result in osteoporosis in experimental animals.

FDA did not receive any comments on this proposed regulation. However, the agency did receive several comments that suggested that disqualifying levels be set for minimum nutrient content, sugars, saccharin, food colors, and various other food additives. These comments are discussed in section II.G.3. of this document (see comments 25 and 26 of this document) and further in this section in response to comment 87 of this document.

D. Infant Foods

Proposed § 101.14(e)(5) provided that no food may bear a health claim if it is represented or purports to be for infants and toddlers less than 2 years of age.

86. One comment questioned the prohibition of health claims on foods promoted for use by infants and toddlers. The comment asserted that claims for all infant formulas, including those formulas that are not subject to the requirements of section 412(h) of the act (i.e., "nonexempt" infant formulas), were meant by Congress to be regulated solely under section 412. More specifically, the comment contended that the agency has already successfully used the premarket notification process of section 412(d) of the act to obtain substantiation of claims from manufacturers of both exempt and nonexempt infant formulas. Further, the comment asserted that the notification process provides the agency adequate oversight of claims for all infant formulas, in keeping with the intent of the requirements for health claims in the 1990 amendments, without impeding product innovation or denying access to product information. Accordingly, the comment recommended deleting proposed § 101.14(e)(5) and revising proposed § 101.14(f)(1) to exclude nonexempt infant formulas, in addition to exempt formulas, from the requirements in that section for health claims.

Another comment viewed a total ban on infant food health claims as an abridgement of commercial free speech protected by the First Amendment. The comment suggested that a more acceptable approach would be to require explanatory information to accompany such claims in order to eliminate any consumer misconceptions.

Although section 403(r)(5)(A) of the act excludes exempt infant formulas from the requirements in section 403(r) for health claims, the 1990 amendments are silent on the applicability of section 403(r) to health claims for nonexempt infant formulas. Thus, health claims on such products are subject to the requirements of section 403(r) of the act. However, in the proposal on general requirements for health claims, FDA pointed out that it had received a letter from the American Academy of Pediatrics that expressed concern that a health claim directed to adults may be inappropriate or harmful to infants and young children (56 FR 60537 at 60556). The letter pointed out that where health claims primarily embody dietary recommendations for the adult U.S. population to reduce the risk of chronic, degenerative diseases, such recommendations are not meant to apply to infants and young children. "Nutrition and Your Health—Dietary Guidelines for Americans" (Ref. 7) states, for example, that the guidelines are "advice for healthy Americans ages 2 years and over—not for younger children and infants, whose dietary needs differ." Accordingly, the agency proposed in § 101.14(e)(5) to prohibit a health claim in labeling of a food represented or purported to be for infants or children less than 2 years of age. The proposed prohibition would have applied to nonexempt infant formulas.

In view of the concerns expressed by the comments, FDA has reconsidered the propriety of health claims on infant food. The agency now believes that the proposed prohibition on infant and toddler foods may have been overbroad. Although health claims based on current dietary recommendations for Americans do not include infants and toddlers, FDA believes that Congress did not intend to limit health claims to only the adult population or to diseases affecting only that population. Thus, the agency cannot discount the possibility that, in the future, information may be developed to support a claim appropriate for infants and young children on the relationship between a substance and a disease or health-related condition. A claim that characterizes this substance-disease relationship would meet the definition for a health claim and thus be subject to the requirements of section 403(r) of the act. The agency has therefore revised new § 101.14(e)(5) to provide for exceptions from the prohibition of infant and toddler health claims when a regulation has been established in part 101, subpart E.

However, the agency has the option, and believes that it may be more prudent, to regulate claims for infant and toddler foods under sections 403(j) and 411(c) of the act, which deal with foods for special dietary use. Thus, should the agency receive a petition that appears to justify a health claim directed to infants and toddlers under section 403(r) of the act, it will decide how best to proceed to authorize the inclusion of the information in the food label.

The agency disagrees with the contention that health claims for nonexempt, as well as exempt, infant formulas should be exempt from section 403(r) of the act and be subject only to the requirements of section 412 of the act. Congress specifically chose to exclude only exempt infant formulas from section 403(r) of the act. Section 412 of the act, although specific to infant formulas, does not exclude such formulas from requirements that are based on other parts of the act. Hence, a labeling claim for an exempt or nonexempt infant formula may be found to misbrand the product under section

403(a) or (j) of the act. In addition, a claim for a nonexempt formula, but not an exempt formula, may also be subject to section 403(r) of the act.

Although the agency has reviewed manufacturers' claims to ensure their validity for both exempt and nonexempt infant formulas in premarket notifications submitted in compliance with section 412 of the act, the agency's conclusions were based on compliance with all applicable sections of the act, not just section 412. The agency is obliged to administer the act as a whole. Because section 412 of the act is not the only section governing labeling for infant formulas (see section 412(e)(1)(B)), the agency must reject the comment's recommendation that health claims requirements in proposed § 101.14 not apply to nonexempt infant formulas.

In light of the agency's conclusion that it will consider health claims for infant and toddler foods, where appropriate, and will establish specific regulations providing for their use, the constitutional issue of a ban on health claims for such foods is now moot. New § 101.14(e)(5) has been revised to prohibit only those claims on infant and toddler foods that are not specifically provided for in part 101, subpart E. Comments that have raised constitutional questions will be dealt with at length later in this document.

E. Additional Limits on Health Claims

87. Some comments urged the agency to allow health claims only on foods that are consistent with dietary guidelines. A number of these comments suggested that this could be done by prohibiting health claims on foods with insignificant amounts of all nutrients required on the label (e.g., coffee), as well as on candies, soft drinks, and other snack foods characterized as not being recognized as part of a sound dietary pattern. However, comments from the snack food industry protested such limitations on health claims and maintained that any food that provides a "high" (or "low") level of a nutrient without exceeding the disqualifying levels for fat, saturated fat, cholesterol, and sodium can be consumed within the framework of a healthy diet and should be allowed to bear health claims.

FDA is not persuaded that a prohibition from bearing a health claim based on a food's categorization or characteristic use—such as a snack food—is in keeping with the intent of the statute. The House Report (Ref. 1) contains an example intended to illustrate the Secretary option to decide whether to grant an exception from a disqualifying nutrient level in the context of the total daily diet. The example compares a frozen dinner with a snack food, both with a particular level of fat, and suggests that the frozen dinner may be considered sufficiently more significant in the total daily diet than the snack food. Implicit in this example, however, is a recognition by Congress that snack foods would be able to bear health claims if they did not contain a level of a nutrient that exceeds the disqualifying level. Thus, the agency concludes that Congress did not intend that snack foods or other foods that could be in general use in the diet should be subject to a per se prohibition on bearing a health claim.

However, as FDA explained earlier in this preamble in its response to comment 23 of this document, Congress intended that FDA establish provisions of health claims regulations by considering the role of the nutrients in food in a way that will enhance the chances of consumers constructing total daily diets that meet dietary guidelines. Thus, FDA finds merit in the suggestion that foods bearing health claims should be those consistent with dietary guidelines, and that the value of health claims should not be trivialized or compromised by their use on foods of little or no nutritional value. The agency, therefore, agrees that the final rule should be modified in some way to more fully assure consistency with dietary guidelines.

Dietary guidelines do stress the importance of selecting foods so that dietary sources of calories are coupled with sources of nutrients. FDA specifically notes that "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 7) states that foods that supply calories but are limited in nutrients should be used in moderation. Furthermore, the recommendations provided in "USDA's Food Guide Pyramid" (Ref. 29) expand on this approach to food selection. Given the requirement in section 403(r)(3)(B)(iii) of the act that states that a claim should enable the public to comprehend the information in a claim and understand the relative significance of that information in the context of a total daily diet, FDA concludes that it is appropriate to provide a basis for health claims that takes into account the nutritional contribution of the food beyond its role as a source of calories. Without such a criterion, foods that are not compatible with dietary guidelines could bear health claims. The claim would promote the consumption of the food but would fail to set the food in its proper dietary context. In addition to being inconsistent with section 403(r) of the act, claims intended to promote the consumption of a food that is incompatible with dietary guidelines would be misleading to consumers and, thereby, be in violation of section 403(a). Such claims would be misleading because consumers would be purchasing the food, in part, to achieve a more healthful diet. However, foods inconsistent with dietary guidelines should not be associated with the more healthful diets recommended by Federal agencies that are mentioned above.

Therefore, in addition to the requirements in new § 101.14(d)(vi) and (d)(vii) for content in a food of a substance that is the subject of a health claim, the agency has developed an approach that would limit health claims to foods that contribute certain nutrients to the diet and, thus, are sources of more than calories. This approach incorporates established levels of significance for nutrients in food and is based on the amounts in foods of certain nutrients required to be listed on the label as part of mandatory nutrition labeling. As such, this approach applies to all foods in conventional food form.

Dietary supplements not in conventional food form are not subject to this requirement. Such supplements are not intended to provide more than nutritive value to the daily diet and make no pretense that they should serve as substitutes for conventional food. As a result it would not be logical to hold such products to criteria designed to assure consistency with dietary guidelines for conventional food. A dietary supplement that meets the qualifying criterion in proposed § 101.14(d)(2)(vii) and does not contain a nutrient at a disqualifying level specified in proposed § 101.14(a)(5) possesses nutritive value for a health claim irrespective of whether or not it may also provide calories. (FDA is including the exception for dietary supplements in § 101.14(e) because under section 202(b) of the DS Act, the agency can approve claims for such products).

The final rule for mandatory nutrition labeling published elsewhere in this issue of the **Federal Register** requires the listing of 12 nutrients apart from calories as follows: Total fat, saturated fat, cholesterol, total carbohydrates, sugars, fiber, protein, sodium, vitamin A, vitamin C, calcium, and iron. As described in that document, FDA concluded that these nutrients are of sufficient public health importance to warrant their inclusion in the nutrition label. Therefore, these same nutrients provide an appropriate basis for a criterion intended to preclude health

claims on foods that do not make a nutritional contribution to the diet and thus are inconsistent with dietary guidelines. This conclusion is supported by comments that suggested that FDA should establish such a criterion based on the nutrients required in the mandatory listing on the food label.

Of the 12 mandatory nutrients, vitamin A, vitamin C, iron, calcium, protein, and fiber constitute nutrients for which the levels in foods can serve as a basis for determining a food's nutritional contribution to the overall diet. Total fat, saturated fat, sodium, and sugars are nutrients for which the current recommendations are to limit intake. Therefore, the presence of the latter nutrients in a food would not provide an appropriate basis for measuring the positive contribution of a food to the diet. While total carbohydrates reflects the contribution to the diet of complex carbohydrates, a nutrient for which current recommendations are to increase intake, it also reflects the contribution of sugars for which current recommendations are to limit intake. Therefore, total carbohydrates is not an appropriate component of a nutritional contribution criterion.

The final rule on nutrient content claims published elsewhere in this issue of the **Federal Register** states that a food is a good source of a nutrient when the nutrient is present in the food at a level of 10 percent or more of the label reference value. The agency concludes, therefore, that this defined level is an appropriate basis for a criterion to measure the nutritional contribution of a food. Therefore, assuming that a food meets the definitions prescribed in this final rule for bearing a health claim, the food must also contain one or more of the six nutrients listed above (vitamin A, vitamin C, iron, calcium, protein, or fiber) in an amount at or above 10 percent of the Reference Daily Intake (RDI) or DRV per reference amount customarily consumed for that nutrient. Based on a review of the regulatory food composition data base (Ref. 33), the agency notes that most foods consistent with dietary guidelines meet this criterion.

Furthermore, in order to preclude the fortification of foods solely for the purpose of making a claim, the nutrient or nutrients must not be derived from fortification or other additions to the food. Fortification of a food of little or no nutritional value for the sole purpose of qualifying that food for a health claim is misleading for several reasons. There is great potential to confuse consumers if foods like sugars, soft drinks, and sweet desserts are fortified to qualify for a health claim when, at the same time, dietary guidance as contained in USDA's Food Guide Pyramid (Ref. 29), for example, states that "[T]hese foods provide calories and little else nutritionally. Most people should use them sparingly." Indiscriminate fortification of such foods with one nutrient would not make such foods consistent with dietary guidelines. Further, fortifying such foods is not consistent with FDA's fortification policy in § 104.20 that has been in effect for many years. The fundamental objective of FDA's policy on appropriate fortification of foods is to establish a uniform set of principles that serve as a model for the rational addition of nutrients to foods. In that policy, FDA clearly states its concern that random fortification of foods could result in deceptive or misleading claims for foods. In the document concerning nutrient content claims that appears elsewhere in this issue of the **Federal Register**, FDA is including a provision requiring that added nutrients must be in compliance with § 104.20 for a food to be eligible to bear the term "more" on its label.

FDA stresses that the exclusion of fortification pertains only to fortification to specifically meet the requirements of this provision and not to fortification of the food itself. Thus, a fortified food, including a dietary supplement in conventional food form, may still qualify for a health claim, provided the qualification is not on the basis of that fortification. Accordingly, FDA has added a new § 101.14(e)(6) to require that, except for dietary supplements not in conventional food form, the food shall contain 10 percent or more of the RDI or DRV for vitamin A, vitamin C, iron, calcium, protein, or fiber prior to any nutrient addition.

VII. Exemption of Medical Foods and Exempt Infant Formulas

FDA proposed in § 101.14(f) that medical foods, as defined in section 5(b) of the Orphan Drug Act (21 U.S.C. 360ee(b)), and infant formulas subject to section 412(h) of the act are specifically exempted from requirements for health claims and nutrient content claims. This exemption reflects the exemption in section 403(r)(5)(A) of the act.

FDA received no comments on this aspect of the proposal. Therefore, the agency is adopting this section as proposed.

VIII. Applicability of Health Claims

FDA proposed in § 101.14(g) that the requirements for health claims in proposed § 101.14 only apply to foods intended for human consumption that are offered for sale.

FDA received no comments on this aspect of the proposal. Therefore, this section is being adopted by the agency as proposed.

IX. Petitions

A. Agency Review Period

88. One comment asserted that FDA should not establish any health claim petition provisions because citizen petition regulations in § 10.30 (21 CFR 10.30) are adequate to provide for petitions to FDA that request that the agency authorize a health claim.

FDA disagrees with this comment. Section 403(r)(4)(A)(i) of the act establishes unique statutory procedures for the handling of health claim petitions that are not applicable to the existing citizen petition regulation. The statute has specific timeframes for FDA to evaluate health claim petitions and, unlike the provisions of § 10.30, provides for not releasing the content of a petition if it is denied prior to acceptance for filing. If FDA were to accept health claims petitions in accordance with § 10.30, petitions that the agency denies after its initial 100-day review might be released. Further, FDA believes that a procedural regulation for health claims petitions is necessary so that petitioners will clearly understand what is required, that the agency's review will be conducted on a consistent and equitable basis, and that the grounds for agency action on the petition will be clearly understood.

89. Some comments objected that the timeframes in the petition provisions for FDA assessing the validity of the proposed claim and for issuing a proposed regulation are too rigid. One of these comments suggested that in cases where there is minimal or nonexistent controversy, FDA should streamline the petition approval process. The comment noted that while the statutory filing period gives the agency time to determine whether a proposed claim is valid, that filing period also serves to deprive the public of truthful claims until final approval is granted. The comment suggested that FDA adopt a mechanism to quickly determine whether there is a large consensus among scientists on the validity of a proposed claim and, if so, to shorten the timeframes. However, other comments suggested that longer timeframes are needed so that the agency can review the data and request additional information if needed, after which FDA should allow, modify, or reject the health claim application and notify the applicant.

FDA advises that the agency may not consider longer timeframes for the evaluation of petitions about health claims because the timeframes are specifically established in section 403(r)(4) of the act. These short timeframes do not provide an opportunity for continuing correspondence between the petitioner and FDA. With respect to suggestions for shorter timeframes, FDA advises that the agency's ability to meet timeframes is influenced by many factors such as work priorities and availability of personnel. FDA considers the statutory timeframes for assessing the validity of health claims and for issuing a proposed regulation to be extremely short, given the need to evaluate the totality of available scientific evidence on a substance and a disease. Given the agency's limited resources, it would not be practicable to shorten these timeframes further. However, FDA points out that although action on petitions for most claims will require virtually all of the time provided by the statutory timeframes, nothing would prohibit the agency from acting in less time than the timeframes provide if it is possible to do so. Thus, it is likely that a petition for a claim on a well-accepted substance/disease relationship would be reviewed more expeditiously than one for which scientific agreement is not as clear.

90. Some comments recommended that FDA allow new health claims to be used as soon as the proposal issues, instead of waiting until the final regulation becomes effective. One comment asserted that this approach would greatly benefit the public by quickly disseminating truthful health claim information, and that there would be little risk to consumers from consuming additional amounts of a food if the health claim is eventually denied.

The agency advises that there is no basis under the act to provide for the use of proposed health claims. Section 403(r)(1)(B) of the act deems a food misbranded when its label or labeling bears a health claim unless the claim is made in accordance with section 403(r)(3) or (r)(5)(D). Section 403(r)(3) and (r)(5)(D) of the act requires that the health claim be made in accordance with regulations. Proposed rules are not "regulations."

Further, even if FDA had a basis under the act to permit the use of proposed health claims, the agency does not believe that it would be prudent to provide for such use. The comment period following the publication of proposed rules is a critical step in determining whether a proposed regulation is appropriate for adoption. In the instance of health claim regulations, significant information concerning validity of the substance-disease relationship underlying the proposed health claim may be submitted by interested parties during the comment period. In addition, the comment period may bring to light a previously unforeseen potential for the health claim to be misleading to consumers if adopted without modification.

B. Public Disclosure

91. Some comments expressed concern regarding public release of private or proprietary data submitted as part of a health claim petition. Other comments agreed with the proposal as written in § 101.70(j)(2) on the grounds that allowing the public to scrutinize information submitted in a petition will help ensure that the evidence is scientifically sound and unbiased.

Section 403(r)(3)(B)(i) of the act mandates that the Secretary (and FDA, by delegation) determination as to whether to authorize a health claim be based on the totality of "publicly available evidence." Moreover, section 403(r)(4)(A)(i) of the act provides for not making a petition available to the public only when FDA decides to deny it without filing it. Consequently, FDA does not have authority to withhold this information from public scrutiny and will make all information submitted in support of a health claim publicly available when the petition is filed.

C. Preparation of Model Health Claim

92. One comment objected to the petitioner having to propose model health claims, asserting that the format and wording of model health claims should be the responsibility of FDA. The comment stated that the 1990 amendments did not require the petitioner to prepare model health claims. Another comment, however, endorsed the proposal that a petitioner include a model health claim, because it will promote efficiency by giving FDA a starting point and ensure that the petitioner is planning to use the claim to promote the public's health.

FDA agrees with the latter comment. Because the petitioner should be one of the parties most knowledgeable about the relevant substance-disease relationship, the agency does not believe that requiring the inclusion of a model health claim will constitute a significant burden on the petitioner. Such a requirement will, however, provide significant benefit by ensuring that the agency can easily and correctly identify what the petitioner believes to be the full substance-disease relationship within the short review timeframes.

D. Summary of Scientific Data

93. Some comments argued that unpublished research findings, including proprietary data, should be considered in support of proposed health claims. However, a number of comments disagreed asserting that only data suitable for publication and data already accepted for presentation in a scientific community would be suitable for the substantiation of health claims.

FDA will consider all unpublished findings that are submitted in support of proposed health claims. Although the agency will consider such findings, FDA points out that, as suggested in the legislative history (Ref. 1), the agency may give greater weight to a research report published in a peer-reviewed journal because such reports have been subjected to scientific evaluation before publication. The agency is likely to give greatest weight, however, to research reports of well-conducted, relevant studies regardless of publication status.

E. Denial of Petitions

94. A number of comments stated that if the agency is to deny a petition without filing it, FDA should do so based on a review of the petition as a whole. One comment said that even if the "Preliminary Requirements" section of the petition is inadequate FDA should still examine the "Summary of Scientific Data." The comment stated that if the agency did so, and discussed that review in the denial notice, it would provide the petitioner with some indication as to whether a redrafted petition would be justified. The comment contended that such a procedure would be more efficient in the longrun and presumably would save FDA from having to review repeatedly submitted petitions.

FDA does not believe that it would be prudent to adopt a general policy of conducting exhaustive reviews of petitions that are to be denied because they fail to meet preliminary requirements. The denial of a petition on the grounds that the preliminary requirements are not met would reflect a fundamental problem with the petition. Such problems may take a fair amount of time to remedy. Therefore, to ensure that it uses its resources most effectively and efficiently, FDA will not undertake an evaluation of the scientific validity of a claim unless the preliminary requirements are satisfied.

95. Several comments dealt with the language of the regulation disapproving the health claim. They particularly disapproved of the language "FDA has

concluded that there is no basis for claims about the following * * *." The comments suggested alternate wordings for proposed § 101.71 that would recognize that "although there is considerable interest in these areas, and although new evidence is continually emerging, the data are not yet strong enough to permit approval of health claims for the reasons summarized below." The comments stated that this language should be followed by an enumeration of the disapproved claims together with a short paragraph describing both the strength and the perceived shortcomings of the evidence in each case. This approach would, according to comments, establish an appropriate record of FDA's determination, without unnecessarily damaging any of these active areas of scientific research.

FDA agrees with the comments that there should be some codified record of its consideration of the health claims on which it proposed action, either in response to the 1990 amendments or a petition, but ultimately decided not to authorize. That record is provided by the citation to the final rule denying the health claim that is included in the listing in new § 101.71. The discussion in the preamble to the final rule summarizes the agency's consideration of the claim. Thus, the agency does not believe that paragraphs describing the strengths and shortcomings of the evidence regarding specific health claims are needed in the codified language to "establish an appropriate record of FDA's determinations."

The agency disagrees that a negative decision regarding a particular health claim will be damaging to active areas of scientific research. It is obvious that the extensive literature regarding the complex relationships between substances and diseases and health-related conditions developed without consideration of whether specific health claims on particular foods might be allowed at some time in the future. FDA's denial is just as likely to highlight the matters on which further research is needed as it is to damage the prospects for further research. However, for greater clarity, the agency has revised the statement in new § 101.71 that there is "no basis for claims" to state that there is "not a sufficient basis for claims * * *."

F. Other Petition Issues

96. Another comment urged that FDA not redelegate to the Director and Deputy Director of CFSAN all the functions of the Commissioner concerning petitions for label claims under section 403(r) of the act that do not involve controversial issues. The comment stated that all petitions that will be submitted to the agency concerning health claims will involve controversial issues that will require a response from the Commissioner.

FDA does not agree. Based on the agency's experience with petitions that have been submitted to FDA for consideration, it is not uncommon for a petition to contain major deficiencies that necessitate denial of the petition. The agency believes that redelegating such functions to the Director and Deputy Director of CFSAN will permit the agency to take the required actions (e.g., denial of a petition) in the most resource efficient manner.

Further, the agency does not agree that it should assume that all petitions submitted under section 403(r) of the act will involve controversial issues. The agency should have the prerogative to take action on a petition in the most resource efficient manner. For example, in the future, it is certainly possible that some substance-disease relationships will become established, and that there will be no controversy about the scientific basis for a claim. If such a situation occurs, the agency should have the flexibility to authorize information about such relationships in food labeling in an efficient manner. Therefore, the agency is retaining the redelegation provision in the final rule.

X. Constitutional Issues

A. The First Amendment

97. Several comments from industry and nonprofit organizations asserted that truthful information about health and diet consists of speech protected under the First Amendment, and at the very least is protected commercial speech. According to the comments, such truthful information encompassed a wide variety of labeling information ranging from information that FDA classifies as a "health claim" to general information about what food categories should be included in a diet to affect disease that FDA classifies as "dietary guidance." (As explained previously in this preamble, for the sake of clarity in this preamble, references by FDA to "dietary guidance" will refer to claims that do not contain both basic elements of a health claim and are therefore not "health claims.") Comments stated that the commercial speech doctrine recognizes that such speech not only serves the economic interests of the speaker but assists consumers and furthers society's interest in "the fullest possible dissemination of information." Therefore, while such speech is entitled to less protection than other forms of expression, that protection is nonetheless substantial. Several comments cited case law that stated that if the commercial expression at issue is neither false nor misleading, then any regulation restricting it must directly advance the governmental interest asserted and must be no more extensive than necessary to serve that interest. Comments contended that any suggestion that consumers should be screened from truthful information "in their own best interest" is the type of paternalism rejected by the Supreme Court in *Virginia State Bd. of Pharmacy* v. *Virginia Citizens Consumer Council Inc.*, 425 U.S. 748 (1976), and the concept that the public cannot be trusted to make valid judgments based on truthful information contravenes the basic principles of the First Amendment. Comments asserted that the public interest and, indeed, the public right is in obtaining useful information, and the government's interest is best served by placing no barriers to its free circulation. Another comment specifically requested that FDA clarify how the health claims regulations comply with Supreme Court standards for constitutionally protected civil or commercial speech.

However, other comments stated that the health claim regulations do not violate manufacturers' First Amendment rights, because food labels that are not in compliance with the act are inherently misleading and therefore not entitled to constitutional protection. The comments argued further that, even if a court found that a nonconforming health claim was not misleading, it would uphold these regulations because they are tailored specifically to meet the substantial Government interest of protecting the public.

FDA advises that neither these regulations, nor the act as amended by the 1990 amendments, violate the First Amendment. The act has withstood numerous First Amendment challenges. (See, for example, *United States* v. *General Nutrition, Inc.*, 638 F. Supp. 556, 562 (W.D.N.Y. 1986); *American Frozen Food Institute* v. *Mathews*, 413 F. Supp. 548 (D.D.C. 1976), aff'd, 555 F.2d 1059 (D.C. Cir. 1977); *United States* v. *Articles of Food* * * * *Clover Club Potato Chips*, 67 F.R.D. 419 (D. Idaho 1975); *United States* v. *8 Cartons, Containing Plantation The Original etc. Molasses*, 103 F. Supp. 626 (W.D.N.Y. 1951).) The 1990 amendments amended the act to permit certain information about the relationship of nutrients in food and disease to appear on a food label without misbranding the food under section 403 of the act or transforming it into a drug under section

201(g)(1)(B) of the act. The regulations implementing these amendments thus permit more information on food labels than has previously been allowed under the act.

Nonetheless, parts of the act and these regulations may have an incidental effect on speech in a narrowly defined area, food labeling. (See *NAACP* v. *Claiborne Hardware Co.*, 458 U.S. 886, 912 (1982).) The Supreme Court, however, "has recognized the strong governmental interest in certain forms of economic regulation, even though such regulation may have an incidental effect on rights of speech and association." Id. The Government may regulate in areas of economic activity such as securities, antitrust, and labor in ways that affect speech. *SEC* v. *Wall Street Publishing Institute*, 851 F.2d 365, 372–73 (D.C. Cir. 1988), cert. denied, 489 U.S. 1066 (1989); see also *SEC* v. *Suter*, 732 F.2d 1294, 1299 (7th Cir. 1984) (the First Amendment does not remove a business engaged in the communication of information from general laws regulating business practices). The Government "does not lose its power to regulate commercial activity deemed harmful to the public whenever speech is a component of the activity." *Ohralik* v. *Ohio State Bar Association*, 436 U.S. 447, 456 (1978); see also *Home Box Office, Inc.* v. *FCC*, 567 F.2d 9, 46 (D.C. Cir. 1977), cert. denied, 434 U.S. 829 (1977) ("[R]ules restricting speech do not necessarily abridge freedom of speech.")

As with securities, labor, and antitrust regulation, the Government exerts extensive regulatory authority over the economic activity surrounding food and its labeling. Yet the regulation of food and food labeling clearly encompasses more than mere economic activity: It protects consumer health and safety in an area where harm to the public can be direct and immediate. (See *Ohralik*, 436 U.S. at 456.) FDA's crucial role in ensuring that food labels are informative, are not misleading, and do not otherwise misbrand products under the act has long been recognized. (See 79 Congressional Record 4734 (1935), reprinted in "Dunn, Federal Food, Drug, and Cosmetic Act," 280 (1938) (statement of Sen. Copeland) ("No one disputes that the [FDA] should determine the quality of the product; no one disputes that it should determine what is on the label.")) In such an area of extensive Federal regulation, the Government may place restrictions on speech that bears directly on the Government's objectives. *SEC* v. *Wall Street Publishing Institute*, 851 F.2d at 373. Indeed, regulation of food labeling would be impossible if the Government could not restrict speech. Id.

Thus, when FDA seeks to ensure that food is not misbranded, it may place restrictions on label contents. "Freedom of Speech does not include the freedom to violate the labeling provisions of the Federal Food, Drug, and Cosmetic Act." *United States* v. *Articles of Food * * * Clover Club Potato Chips*, 67 F.R.D. 419, 424 (D. Idaho 1975). "[C]ertain speech in a certain limited context" becomes part of the labeling of a product and may serve as evidence of a violation of the act. *United States* v. *General Nutrition, Inc.*, 638 F. Supp. 556, 562 (W.D.N.Y. 1986). Thus, the seizure and condemnation of a book that misbrands a product is not a violation of the First Amendment, even though in another context the book might be protected. (See *United States* v. *8 Cartons, Containing Plantation The Original etc. Molasses*, 103 F. Supp. 626, 628 (W.D.N.Y. 1951); *United States* v. *Article of Drug*, 32 F.R.D. 32 (S.D. Ill. 1963).) "It is the product and the manner in which the product is marketed which is said to be illegal," rather than the speech itself. *General Nutrition*, 638 F. Supp. at 562. A prohibition on selling a misbranded product restrains the violative act of selling, not speech itself. *Kellogg Co.* v. *Mattox*, 763 F. Supp. 1369, 1381 (N.D. Tex. 1991) (construing Texas food and drug law). "The substantial government interest in the goals of the Act justif[ies] this extremely narrow encroachment" on speech. *General Nutrition*, 638 F. Supp. at 562. Indeed, where certain claims misbrand a product, "[a] requirement that the claims be removed, in order to sell the product, is certainly less restrictive than a flat prohibition of the sale of the product." *Kellogg*, 763 F. Supp. at 1381.

With the provisions of the 1990 amendments that govern health claims, Congress sought to "permit health claims but only health claims based on scientifically valid information." (statement of Rep. Waxman; Ref. 4). In order to assist consumers improving their eating habits, Congress devised a scheme to permit certain claims not previously allowed under the act. Under this scheme, only those claims that FDA finds to be "supported by science" are permitted, (statement of Rep. Waxman; Ref. 3), and a food that bears an unapproved health claim is misbranded. Because FDA case law makes clear that a label statement that misbrands a food product is not subject to First Amendment protection, an unapproved health claim on a food label would not be protected speech. (See *United States* v. *General Nutrition, Inc.*, 638 F. Supp. 556 (W.D.N.Y. 1986); *United States* v. *Articles of Food * * * Clover Club Potato Chips*, 67 F.R.D. 419 (D. Idaho 1975); *United States* v. *8 Cartons, Containing Plantation The Original etc. Molasses*, 103 F. Supp. 626 (W.D.N.Y. 1951); *United States* v. *Article of Drug*, 32 F.R.D. 32 (S.D. Ill. 1963).)

Congress considered the use of "unfounded" health claims on the food label to be harmful to the public (statement of Rep. Waxman; Ref. 3); cf. *Ohralik*, 436 U.S. at 456 ("[T]he State does not lose its power to regulate commercial activity deemed harmful to the public whenever speech is a component of that activity.") Congress dealt with this problem by crafting a system to permit certain useful information to appear on the food label, while ensuring that the information is scientifically valid and not misleading (statement of Rep. Waxman; Ref. 4). Congress considered these restrictions on speech necessary to further the Government's interest in ensuring the scientific validity of health claims on the food label. The Government's action in regulating the food label does not offend the First Amendment simply because speech is involved. *Ohralik*, 436 U.S. at 456. The case law establishes that FDA's power to regulate the food label derives from its broad regulatory powers over food, and these regulations are valid under the limited scrutiny that has been afforded restrictions on speech under extensive regulatory schemes involving areas of economic activity. (See *SEC* v. *Wall Street Publishing Institute*, 851 F.2d at 372–73; see also *Dun & Bradstreet, Inc.* v. *Greenmoss Builders*, 472 U.S. 749, 785 n.5 (1985); *Ohralik* v. *Ohio State Bar Association*, 436 U.S. 447, 456 (1978).)

Many comments argued that labeling is commercial speech, and that restrictions placed on it must pass the tests enunciated by the Supreme Court in cases involving commercial speech. Unlike "advertising pure and simple," labeling does not fall clearly within the bounds of commercial speech. *Zauderer* v. *Office of Disciplinary Counsel*, 471 U.S. 626, 637 (1985). The agency does not consider it necessary for its First Amendment analysis to determine whether or not food labeling fits the definition of commercial speech. (See *SEC* v. *Wall Street Publishing Institute*, 851 F.2d at 372.) Rather, the agency considers labeling on foods to form "a distinct category of communications in which the government's power to regulate is at least as broad as with respect to the general rubric of commercial speech." *SEC* v. *Wall Street Publishing Institute*, 851 F.2d at 373.

Recognizing, however, that at least one court has categorized labeling as commercial speech, *General Nutrition*, 638 F. Supp. at 562, FDA agrees that labeling should certainly be considered closer to commercial speech than to "pure" speech.

Even if labeling is analyzed as commercial speech, however, these regulations do not violate the First Amendment. First, speech that is inherently misleading is not protected and may be prohibited. *Central Hudson Gas & Electric Corp.* v. *Public Service Commission*, 447 U.S. 557, 563–64 (1980). Secondly, speech that is only potentially misleading may be restricted, so long as the restrictions directly advance a substantial governmental interest and are no more extensive than necessary to serve that interest. Id. at 566. These regulations govern speech that is inherently misleading, health claims on the food label. However, even if such claims are considered to be only potentially misleading, the regulations pass the test enunciated in *Central Hudson*.

Commercial speech receives only limited protection under the First Amendment. (See, for example, *Bolger* v. *Youngs Drug Products Corp.*, 463 U.S. 60, 64–65 (1983).) For commercial speech to be protected, it must concern lawful activity and not be misleading. *Central Hudson*, 447 U.S. at 563 through 564. The Supreme Court has recognized that restrictions on commercial speech may be appropriate to prevent deception. *Virginia State Board of Pharmacy* v. *Virginia Citizens Consumer Council*, 425 U.S. at 771 n.24. These regulations will have the effect of ensuring that the health claims that appear in food labeling are scientifically valid and not misleading. (See *American Frozen Food Institute* v. *Mathews*, 413 F. Supp. 548, 555 (D.D.C. 1976), aff'd, 555 F.2d 1059 (D.C. Cir. 1977)) (FDA regulation constituted the agency's conclusion "that labeling which fails to meet the requirements of the regulation is misleading or otherwise not in compliance with the act," and as such it did not violate the First Amendment).

The Supreme Court has labeled as misleading—and thus not protected—both speech that is inherently likely to deceive and that "experience has proved * * * is subject to abuse." In re *R.M.J.*, 455 U.S. 191, 203 (1982). For example, in *Friedman* v. *Rogers*, 440 U.S. 1, 14–15 (1979), the Court held that Texas could prohibit the use of trade names by optometrists where there was a history of deception and abuse of the public. See also *Ohralik* v. *Ohio State Bar Association*, 436 U.S. 447, 468 (1978) (upholding state bar's rules against in-person solicitation where there was an inherent potential for abuse and prophylactic regulation was needed).

By enacting the 1990 amendments, Congress sought to ensure that health claims would be scientifically valid and not misleading. (See, for example, statement of Rep. Madigan, and statement of Rep. Waxman, Ref. 4). Experience had shown that many "unfounded" health claims were being used on foods (statement of Rep. Waxman; Ref. 3). Congress recognized the "great potential for defrauding consumers if food is sold that contains inaccurate or unsupportable health claims." Id. (statement of House floor managers).

In response to the high potential for health claims to be misleading, Congress legislated that any claim that is not consistent with FDA regulations will misbrand a food. Section 403(r)(1)(B) of the act states that a food is misbranded if its label or labeling contains a claim that "expressly or by implication * * * characterizes the relationship of any nutrient * * * of the food to a disease or a health-related condition *unless* the claim complies with regulations promulgated by FDA. § 403(r)(1)(B)" (emphasis added). By taking this approach, Congress chose to permit only those health claims on food that FDA determines to be scientifically valid, effectively recognizing that health claims are so potentially misleading as to be inherently misleading.

Indeed, particular attributes of health claims on the food label make them inherently misleading. Because health claims are of great importance to the public, they have a great potential to be deceptive: Representations relating a product to an issue of public concern as a means to induce consumer purchases may take on increased importance in the mind of the public and thus be more likely to mislead. *FTC* v. *Pharmtech Research, Inc.*, 576 F. Supp. 294, 301 (D.D.C. 1983) (advertisements for food supplement were misleading where they "played on the average consumer's well-founded fear of cancer"). A health claim on a food label is the type of information that a consumer would have difficulty verifying independently. *American Home Products* v. *FTC*, 695 F.2d 681, 698 (3d Cir. 1982); cf. *Peel* v. *Attorney Reg. & Disciplinary Commission*, 496 U.S. 91, 110 S. Ct. 2281, 2288 (1990) (a lawyer's certification is a "verifiable fact"). Consumers place great reliance on the portions of the food label that they believe to be regulated by the Government (Ref. 36). Unapproved health claims that consumers assume to be consistent with government regulations are therefore more likely to be misleading. "Pervasive government regulation * * * and consumer expectations about such regulation, create a climate in which questionable claims * * * have all the more power to mislead." *American Home Products* v. *FTC*, 695 F.2d at 697.

Even if health claims are considered only potentially misleading, rather than actually or inherently misleading, these regulations are constitutional. The government may place restrictions on commercial speech that is merely potentially misleading. Such restrictions must directly advance a substantial governmental interest and be no more extensive than necessary to serve that interest. *Central Hudson Gas & Electric Corp.* v. *Public Service Commission*, 447 U.S. 557, 566 (1980). These regulations pass that test.

First, the government's interest is clearly substantial. The 1990 amendments and these regulations seek to ensure that consumers have access to information about food that is scientifically valid, truthful, reliable, understandable, and not misleading. This information will enable consumers to make more healthful food choices. The Supreme Court has recognized "the health, safety, and welfare of * * * citizens" as a substantial government interest. *Posadas de Puerto Rico Associates* v. *Tourism Co.*, 478 U.S. 328, 341 (1986). Moreover, consumers have a First Amendment interest in obtaining information on which to base a decision whether to buy a product, and this interest is "served by insuring that the information is not false or deceptive." *National Commission on Egg Nutrition* v. *FTC*, 570 F.2d 157, 162 (7th Cir. 1977), cert. denied, 439 U.S. 821 (1978). "The fact that health is involved enhances the interests of both consumers and the public in being assured 'that the stream of commercial information flow clearly as well as freely.'" Id. (citing *Virginia State Board of Pharmacy*, 425 U.S. at 772); *American Home Products*, 695 F.2d 681, 714. Moreover, FDA is implementing legislation whose purpose is "essential if the consumer is to obtain reasonable information regarding * * * the foods he buys." *American Frozen Food Institute* v. *Mathews*, 413 F. Supp. 548 (D.D.C. 1976), aff'd, 555 F.2d 1059 (D.C. Cir. 1977).

Secondly, the regulations directly advance the government interest. Under the 1990 amendments and these regulations, FDA will assess the relevant scientific evidence on a proposed health claim before permitting that claim to

appear on the food label. In this way, the regulations ensure that health claims are scientifically valid, reliable, understandable, and do not mislead consumers. At the same time, the regulatory scheme encourages the provision of information to consumers that will enable them to improve their diets. There is an "immediate connection" between health claims on food labels and consumers' food choices. *Central Hudson*, 447 U.S. at 569.

Finally, these regulations are no more extensive than necessary to serve the government interest. Under *Board of Trustees* v. *Fox*, regulations that are narrowly tailored to serve the government interest will meet this prong of the *Central Hudson* test. 109 S. Ct. 3028, 3032–35 (1989). Narrow tailoring requires a reasonable fit between regulatory ends and means: "not necessarily the single best disposition but one whose scope is 'in proportion to the interest served.'" Id. at 3035. These regulations reasonably and effectively ensure that health claims on food labels will be scientifically valid, informative, and not misleading. (See *Ward* v. *Rock Against Racism*, 109 S. Ct. 2746, 2757–58 (1989).) Thus they meet the third prong of the *Central Hudson* test, and they do not violate the First Amendment.

98. Some comments maintained that dietary guidance may, in appropriate circumstances, be classified as pure speech entitled to constitutional protection, and that merely because speech is presented in a commercial context does not necessarily categorize it as "commercial speech." Thus, for example, "speech is not rendered commercial by the mere fact that it relates to an advertisement." *Pittsburgh Press Co.* v. *Pittsburgh Comm'n on Human Relations*, 413 U.S. 376, 384 (1973). Speech is also "not commercial merely because it proposes a transaction or because there is an economic motivation." *Asian American Business Group* v. *City of Pomona*, 716 F. Supp. 1328, 1330 (C.D.Cal. 1989) (citing *Bolger* v. *Youngs Drug Prods. Corp.*, 463 U.S. 60 (1983)). The consensus of the comments was to conclude that where a manufacturer, either on a label or in package inserts or accompanying brochures, accurately summarizes dietary guidance promulgated by some public health body or medical institution, that message should be treated as noncommercial speech deserving full protection under the First Amendment, and that the such messages are not solely the product of economic motivation.

FDA believes that its approach to dietary guidance, as discussed above, does not raise First Amendment concerns. Dietary guidance on labeling will be considered to fall outside the coverage of section 403(r)(1)(B) of the act, although it would remain subject to other provisions of the act (e.g., sections 403(a) and 201(n) of the act).

FDA disagrees with the comments that argue that certain dietary guidance—e.g., label summaries of information promulgated by a public health body—should be considered pure, noncommercial speech. To the extent that it may be necessary to categorize these statements, FDA believes they should be considered commercial speech. Labeling statements on food products intended for sale would clearly appear in the context of a commercial transaction and would "propose" such a transaction. (See *Bolger* v. *Youngs Drug Products*, 463 U.S. 60, 66, 103 S. Ct. 2875, 2880 (1983); *Central Hudson Gas* v. *Public Service Commission*, 447 U.S. 557, 562 n.5, 100 S. Ct. 2343, 2349 n.5 (1980).) A label is not entitled to the protection due noncommercial speech simply because it contains a discussion of an issue of broad public interest. *Board of Trustees* v. *Fox*, 109 S. Ct. 3028, 3032 (1989); *Bolger*, 463 U.S. at 68, 103 S. Ct. at 2881; *Central Hudson*, 447 U.S. at 562 n.5, 100 S. Ct. at 2349 n.5. Nor is dietary guidance that discusses a product generically, rather than by specific name, exempt from categorization as commercial speech. *Bolger*, 463 U.S. at 66 n.13, 103 S. Ct. at 2880 n.13. And in determining whether the statements on a label are pure speech, it is irrelevant that they might be considered protected in other contexts. (See *Zauderer* v. *Office of Disciplinary Counsel*, 471 U.S. 626, 637 n.7, 105 S. Ct. 2265, 2274 n.7 (1985).) Just as informational pamphlets were considered commercial speech in *Bolger*, so too dietary guidance on food labels should be considered commercial speech. (See *Bolger*, 463 U.S. at 66–68, 103 S. Ct. at 2880–81.)

99. Some comments suggested that the proposed regulations were in conflict with the First Amendment because it protects manufacturers from burdensome and unnecessary labeling requirements.

FDA disagrees with the comments' assertion that the agency is imposing unduly burdensome and unnecessary labeling requirements. Nothing in the regulations goes beyond the statutory requirements imposed by the 1990 amendments. In formulating these regulations, the agency has attempted to reach a reasonable balance between the interest in making information available about the relationship between diet and disease and the interest in ensuring that this information is scientifically valid. The regulations are narrowly tailored to serve a significant governmental interest and do not violate the First Amendment.

100. A number of comments recommended that foods exceeding a disqualifying nutrient level be allowed to bear an approved health claim if they also bear a statement disclosing the level of the disqualifying nutrient. Comments contended that the legislative history of the 1990 amendments clearly establishes Congress' intent to require increased information and disclosure on food labels, and that section 403(r)(3)(A)(ii) of the act is consistent with this approach. Some comments argued that this procedure is consistent with the public's "right to know" and the manufacturers' First Amendment rights to present consumers with information that is truthful and not misleading. Most maintained that the First Amendment principles discussed under the Preliminary Health Claims and Dietary Guidance sections also prohibit FDA from using disqualifying levels to ban health claims on products.

FDA agrees that section 403(r)(3)(A)(ii) of the act gives it the ability to permit approved health claims on foods exceeding a disqualifying nutrient level if they bear a statement disclosing the level of the disqualifying nutrient. The agency "may by regulation permit * * * a claim based on a finding that such a claim would assist consumers in maintaining healthy dietary practices" (section 403(r)(3)(A)(ii) of the act).

FDA disagrees, however, with the implication expressed by the comments that it should permit approved health claims for all foods exceeding a disqualifying nutrient level if their labels disclose the level of the disqualifying nutrient. The agency will permit such claims on a case-by-case basis, when it finds that a claim would assist consumers in maintaining healthy dietary practices. Reading the statute to mandate disclosure rather than disqualification would ignore the terms of the statute and would be inconsistent with Congress's intent. When the bill that became the 1990 amendments was reported out of committee in the House, the prohibition in section 403(r)(3)(A)(ii) of the act on health claims was on food containing "any nutrient in an amount which increases to persons in the general population the risk of a disease or health-related condition which is diet related, taking into account the significance of the food

in the total daily diet." H. Rept. 538, 101st Cong., 2d sess. 5 (1990). Subsequently, while the bill was awaiting passage in the House, language was added to section 403(r)(3)(A)(ii) of the act permitting the agency to exempt certain foods from the prohibition (statement of Rep. Waxman; Ref. 4). Had Congress chosen to require disclosure rather than disqualification in all cases, it could have done so explicitly rather than providing for exceptions to the general rule.

In its proposal, the agency noted that "a health claim on a food label is a promise to consumers that including the food in a diet, along with other dietary modifications, will be helpful in attaining the claimed benefit and will not introduce a risk of another disease or health-related condition" (56 FR 60537 at 60544). Including a health claim on the label of a food that contains unhealthful levels of nutrients would be misleading, and the First Amendment permits the government to ban misleading speech. *Central Hudson Gas & Electric Corp.* v. *Public Service Commission*, 447 U.S. 557, 566 (1980). FDA recognizes that the Supreme Court has expressed a preference for disclaimers or explanations over prohibitions in the context of commercial speech that is merely potentially misleading. In re *R.M.J.*, 455 U.S. 191, 203 (1982). Nothing in these regulations is inconsistent with that approach. Section 403(r)(3)(A)(ii) of the act specifically permits the agency to allow disclosure instead of disqualification where a claim "would assist consumers in maintaining healthy dietary practices." In situations where the government's substantial interest in improving dietary practices would be promoted by permitting disclosure rather than disqualification, and where disclosure would ensure that the health claim was not misleading, FDA will permit disclosure instead of disqualification.

101. Several comments asserted that the First Amendment allows manufacturers to place preliminary health-related statements on labeling as long as those statements are properly qualified. In support of this position, comments cited a series of opinions in *FTC* v. *National Comm'n on Egg Nutrition*, 517 F.2d 485 (7th Cir. 1975), appeal after remand, 570 F.2d 157 (7th Cir. 1977), cert. denied, 483 U.S. 921 (1978). The comments noted that in affirming the grant of a preliminary injunction, the Seventh Circuit held that the Commission could not "prohibit NCEN from stating that there is scientific evidence supporting the theory that dietary cholesterol intake is not unhealthy, provided that it also states that there is substantial contrary evidence." 517 F.2d at 489–490. The comments also noted that the Seventh Circuit struck down an anti-egg warping statement that FTC had asked be mandated in all future advertising, saying that "the First Amendment does not permit a remedy broader than that which is necessary to prevent deception * * * or correct the effects of past deception * * *." The desired preventative effect can be achieved by requiring the disclosure that there is a controversy among the experts and NCEN is presenting its side of that controversy. The additional statement in the form now ordered by FTC should be required only when NCEN chooses to make a representation as to the state of the available evidence or information concerning the controversy." (570 F.2d at 164)

The comments also cited Court of Appeal decisions that followed the Seventh Circuit in requiring a manufacturer to qualify controversial or preliminary claims with statements that a substantial question exists regarding their scientific validity. Bristol-Myers Co., 102 F.T.C. 21, 294–295 (1983), enforced, 783 F.2d 554 (2d. Cir. 1894), cert. denied, 469 U.S. 1189 (1985); American Home Prods. Corp., 98 F.T.C. 136, 333 (1981), enforced as modified, 695 F.2d 681 (3d. Cir. 1982). The comments asserted that FDA policy must therefore allow the inclusion of properly disclosed health claims that are based on preliminary or controversial findings, as long as the studies that led to those findings are sufficiently well-designed and well-conducted to garner "significant scientific agreement" about how the findings should be interpreted.

FDA does not agree that there is a First Amendment right to make preliminary claims on the food label, regardless of the statutory constraints imposed by the 1990 amendments. As discussed in greater detail above, FDA does not have the authority to permit preliminary health claims under section 403(r)(1)(B) of the act. The statutory scheme and these regulations that produce this result do not violate the First Amendment.

As explained above, misleading commercial speech is not protected under the First Amendment. *Central Hudson Gas & Electric Corp.* v. *Public Service Commission*, 447 U.S. 557, 566 (1980). Health claims have such a high potential to be misleading as to be inherently misleading, as Congress recognized when it chose to permit only those health claims on food that FDA determines to be scientifically valid (section 403(r)(1)(B) of the act). In the context of inherently misleading claims, there is no requirement that explanatory information be permitted to eliminate consumers' misconceptions. (See In re *R.M.J.*, 455 U.S. 191, 203 (1982).)

FDA does not agree that it is bound to follow cases involving FTC's regulation of advertising and to permit labeling that presents one side of a scientific controversy, so long as there is a statement that a controversy exists. Although cases involving FTC may sometimes be relevant, it is important to note that fundamental differences exist between the regulatory schemes administered by the two agencies. (See *Bristol-Myers Co.* v. *FTC*, 738 F.2d 554, 559 (2d Cir. 1984), cert. denied, 469 U.S. 1189 (1985).) Congress has long recognized the division of roles between the two agencies. (See 79 Congressional Record 4734 (1935), reprinted in "Dunn, Federal Food, Drug, and Cosmetic Act," 280–281 (1938) (statements of Senators Copeland and Austin) (FTC concentrates on the interests of commerce and economic needs, whereas the objective of FDA is "the health of the people.")) FTC regulates unfair competition and trade practices, including food advertising. (See, for example, 15 U.S.C. sections 45 and 52.) In contrast, FDA is a scientific agency empowered to regulate the food label, among other things. Under section 403(r)(3)(B)(i) of the act, FDA may permit health claims on foods only if it has determined that those claims meet the statutory test for scientific validity. The laws under which FTC operates do not include a comparable statutory standard. Thus, it would not be appropriate for FDA to follow the case law involving FTC.

B. Other Amendments

102. Some comments alleged that outlawing brand names that include an unapproved health claim could violate the Fifth Amendment, as brand names reasonably constitute cognizable private party interests, and banning their use could amount to "taking" those interests without just compensation. Comments warned that the courts have frowned upon banning the use of trade names when less drastic measures would eliminate the possibility of deception. (See In re *R.M.J.*, supra.) (Also, see *Jacob Seigel Co.* v. *FTC*, 327 U.S. 608, 612 (1946) (the policy of the law to protect [brand names] indicates that their destruction should not be ordered if less drastic means will accomplish the same result"").) The comments further suggested that, in keeping with Executive Order 12630 (March 15, 1988), "Governmental Actions and

Interference with Constitutionally Protected Property Rights," FDA should complete a Takings Impact Analysis (TIA) in order to assess whether compensation to the brand name owners would be appropriate, and whether there were viable alternatives to banning the use of the brand names.

In the November 1991 Regulatory Impact Analysis (RIA) (56 FR 60856 at 60865), FDA considered the takings issue and concluded that a TIA was not necessary because the proposed regulations "serve to reemphasize existing regulations as to how products may be named." In view of the comments and concerns raised involving the takings issue, the agency has concluded that it was necessary to conduct the more formalized TIA as set forth in Executive Order 12630. The agency has completed the TIA and concludes that the regulations as set forth below do not present a potential takings. Under the provisions of the Executive Order, the TIA is an internal government decision making document to assist the responsible agency in reducing the likelihood that a "takings" will occur and to provide the decision maker for the agency with information as to any likely cost due to compensable takings. As such, the TIA is not released for public review.

In its November 1991 RIA statement (56 FR 60856 at 60865), FDA stated that the required alteration of trade names did not constitute a taking, and that, as a result, no takings analysis was necessary. FDA still believes that there is no regulatory taking under the Fifth Amendment if a manufacturer is required to alter its brand name when that brand name asserts by implication a relationship between the presence or level of a substance in the food and a disease or health-related condition, and that relationship is not the subject of an approved health claim. These final regulations on health claims constitute a reasonable exercise of the agency's authority to promote policies in the interest of public health. (See *Keystone Bituminous Coal Association* v. *DeBenedictis*, 480 U.S. 470, 488 (1987).) The 1990 amendments made explicit FDA's authority to permit certain health claims if it determines, based on the totality of publicly available scientific evidence, that the claims are scientifically valid. H. Rept. 538, 101st Cong., 2d sess. 9 (1990). The food industry "has long been the focus of great public concern and significant government regulation," and "the possibility was substantial" that the government would, "upon focusing on the issue," decide that the actions now being undertaken are in the public interest. *Ruckelshaus* v. *Monsanto Co.*, 467 U.S. 986, 1009 (1984); see also *Connolly* v. *Pension Benefit Guarantee Corp.*, 475 U.S. 211, 227 (1986) ("Those who do business in the regulated field cannot object if the legislative scheme is buttressed by subsequent amendments to achieve the legislative end.")

Companies that use brand names that contain implied health claims lack a reasonable investment-backed expectation that they will be able to continue to use those names. *Monsanto*, 467 U.S. at 1005. Under the act before the 1990 amendments, and under prior FDA policy, products whose labeling included implied health claims were subject to regulation as drugs without regard to the content of the claim. In 1987, FDA proposed to permit certain health claims on food, but this proposal was never made final and thus cannot be considered to provide the basis for reasonable expectations that specific claims would be allowed. The 1990 amendments for the first time provided companies with the basis for an expectation that certain implied claims, if approved, could be made. Only with the publication of these final rules does the possibility arise that a company might have a reasonable investment-backed expectation in continuing to use an approved claim.

103. One comment noted the possibility that the scientific standard for health claims has the potential to be unconstitutional, either facially or as applied, under the First (manner of application is overbroad and limits constitutionally protected free speech), the Fifth (the vagueness of the standard is such that due process will be violated when organizations are not given fair notice of what conduct is prohibited), the Ninth (without a clearer definition of the standard, oversight of agency actions that exceed its authority would be hindered), and the Fourteenth Amendments.

FDA disagrees with the comment's assertion that these regulations are unconstitutional. As discussed in greater detail at the beginning of this section of this preamble, these regulations do not violate the First Amendment.

FDA further disagrees that the scientific standard is unconstitutionally vague or overbroad, and it questions the applicability of the vagueness and overbreadth doctrines in the current context. The vagueness doctrine is generally applied to strike down prohibitions on speech that leave individuals without clear guidance on the type of speech that is prohibited. (See, for example, *Village of Hoffman Estates* v. *Flipside, Hoffman Estates, Inc.*, 455 U.S. 489, 498–99 (1982); *Grayned* v. *City of Rockford*, 408 U.S. 104, 108 (1972).) This is not the case here. Only approved health claims will be permitted on the food label, and all other health claims will misbrand a food. It will thus be clear which type of speech is prohibited and which permitted. Further, these regulations are narrowly tailored to meet a substantial government interest and are not overbroad. They do not "sweep[] within [their] prohibition what may not be punished under the First * * * Amendment[]." *Grayned*, 408 U.S. at 115. In any event, it is doubtful that the overbreadth doctrine would apply to these regulations, particularly if they were considered to regulate commercial speech, because the overbreadth doctrine does not apply to commercial speech. *Village of Hoffman Estates*, 455 U.S. at 497.

The comment does not explain its reasons for arguing that the regulations violate the Ninth and Fourteenth Amendments, and the agency does not agree that they do so. These regulations do not deny any fundamental rights not enumerated in the Constitution and so do not violate the Ninth Amendment. Because these regulations involve Federal and not State action, the Fourteenth Amendment does not apply.

The agency also disagrees that the regulations violate the due process clause of the Fifth Amendment because organizations will not be on notice of what constitutes prohibited conduct. Under the statutory scheme, as implemented by these regulations, certain health claims will be permitted to appear on food labels without misbranding the food or making the food a drug. No other health claims will be permitted. Organizations will be on notice that the use of an unapproved health claim is prohibited conduct.

The agency also disagrees that Congress has unconstitutionally delegated legislative power to FDA. "Congress does not violate the Constitution merely because it legislates in broad terms, leaving a certain degree of discretion to executive or judicial actors. As long as Congress 'lay[s] down by legislative act an intelligible principle to which the person or body authorized to [act] is directed to conform, such legislative action is not a forbidden delegation of legislative power.'" *Touby* v. *United States*, 111 S. Ct. 1752, 1756 (1991) (citing *J.W. Hampton, Jr., & Co.* v. *United States*, 276 U.S. 394, 409 (1928)).

XI. Consumer Summaries

FDA's 1990 proposal (55 FR 5176), issued prior to the enactment of the

1990 amendments, would have required that a health claim reference a consumer summary that provided full information about the relationship between the food and the disease about which the claim pertained. The summary was intended to facilitate the consumer's assessment of whether the health claim applied to him or her, and, in certain instances, to what extent it applied. The summary was also intended to help alleviate the potential problem of information overload on the label.

In the 1991 proposal for health claims (56 FR 60537), issued in response to the 1990 amendments, FDA suggested that consumer summaries may no longer be necessary. Section 403(r)(3)(B)(iii) of the act provides that the regulation authorizing a claim shall require that the claim be stated in a manner that: (1) Accurately reflects the relationship between a substance and a disease or health-related condition, and the significance of the substance in affecting the disease or health-related condition; and (2) enables the public to comprehend the information provided in the claim and understand the relative significance of such information in the context of a total daily diet. This statutory provision requires that the claim present the most significant aspects of the information that the agency was intending to require in the consumer summaries.

104. Some comments contended that FDA should require or strongly encourage the use of consumer summaries. Several of these comments asserted that their use is necessary to put health claims into the perspective of the total daily diet and alluded to their use as being similar to the package inserts employed for certain drug products. Others stated that their use would be an excellent vehicle for consumer education, and they should be provided and widely disseminated.

However, other comments argued that consumer summaries will have limited benefit in the light of the provisions of the 1990 amendments. Some of these comments stated that any of the proposed health claims will succinctly express the same message originally intended by FDA to be contained in the corresponding summary.

FDA is not persuaded that the use of consumer summaries is necessary in light of the provisions of this final rule. The comments did not contain a basis for the agency to require the summaries. New § 101.14(d)(2) requires, in part, that a health claim that appears in labeling be based on, and consistent with, the authorizing regulation in part 101, subpart E, and that the claim allow the public to understand the information provided in the claim and to understand the significance of that information in the context of a total daily diet. The agency agrees that these requirements fulfill the objectives of the consumer summaries, and that requiring the use of consumer summaries would therefore not be of additional benefit to the consumer. Furthermore, FDA knows of no basis under the act nor any other reason to require more information in the health claim than that that is already required under these rules.

105. Other comments suggested that FDA prepare and distribute a consumer guide containing information on how to use the new nutrition labels and health claim messages to improve eating habits.

Section 2(c) of the 1990 amendments directs the Secretary to carry out activities to educate consumers about the availability of nutrition information in the label or labeling of food and about the importance of that information in maintaining healthy dietary practices. Although FDA has not yet determined all of the measures that it will undertake to fulfill this directive, the agency believes that the guide suggested by these comments would be extremely useful in assisting consumers to achieve healthier dietary habits. Thus, the agency advises that it will prepare such a guide in partial fulfillment of this provision of the law. These comments, as well as those received in response to the 1990 proposal (55 FR 5176), will be considered in developing this guide.

XII. Other Issues

106. One comment objected to allowing a health claim for a nutrient that has been added to a food, arguing not only that the food containing the added nutrient would be subject to undue emphasis in the diet, but that the added nutrient would have a "dilution effect" on the food's naturally-occurring nutrients. The comment made specific reference to added fiber.

FDA disagrees. FDA believes that it is almost always the nutrient content of the diet that is significant, not the source. The comment provided no data to justify a change in the agency's belief. However, wherever the agency becomes aware of a situation in which the relationship of a particular nutrient to a disease or health-related condition is dependent upon the source of the nutrient, FDA will make appropriate provisions in the specific regulation in part 101, subpart E to ensure that the health claim is valid with respect to the source of the nutrient.

107. One comment objected that foods should not be permitted to bear multiple health claims because they might be viewed as "wonder foods." The comment submitted no data to support this position.

The agency has no basis to conclude that multiple valid health claims will be misleading to consumers. To the contrary, FDA believes that if it were to limit the number of different health claims that could appear on the label of a single product, it would place the manufacturer in the position of having to choose which of several valid health claims should appear on the label. Such choices would inevitably lead to a situation where the same food would bear different health claims depending on the particular manufacturer's marketing preferences. Under such circumstances consumers may question which claim was valid, or whether there were differences in the beneficial nutrients in the same food packaged by different manufacturers. Further, if the agency were to restrict the number of health claims on food, such a restriction would be contrary to the Congressional intent of the 1990 amendments that consumers be helped by health claims to maintain a healthful diet (Ref. 1).

108. A comment stated that a manufacturer may occasionally run an offer inviting consumers to submit requests for brochures containing dietary guidance or specific recommendations of a private organization, such as NCI. The comment requested that FDA clarify whether such brochures should conform to the health claims regulations.

For many years, the agency has taken the position that brochures containing nutrition information about a food constitute labeling. For example, § 101.9(f) provides that a statement may be included on the label or in labeling offering additional nutrition information upon written request to a specified address. The provision states further that any additional labeling furnished to consumers or professionals shall comply with all applicable requirements of chapter 1. (The preamble discussion about this provision appears in the response to comment 37 in the Federal Register of March 14, 1973 (38 FR 6950 at 6957).) Accordingly, FDA advises that where a food label contains an offer inviting consumers to submit requests for a brochure, and the brochure explicitly or implicitly characterizes the relationship of a substance to a disease or a health-related condition, the brochure is labeling that contains a health claim and thus must conform to the health claims regulations.

109. Some comments contended that in-store educational programs should not be subject to the health claim regulations. One comment noted that

such programs provide beneficial health and dietary information to consumers and can assist the agency in educating the public about the new labeling initiative. Another comment advised that the guidance in these programs may, or may not, conform to health claims regulations.

FDA recognizes that a wide variety of in-store nutrition education programs incorporating written, printed, or graphic materials, videotapes, or other media, may serve a useful role in assisting consumers maintain a balanced and healthful diet and thereby make a positive contribution toward one of the major goals of the 1990 amendments. Accordingly, the agency wishes to encourage, rather than discourage, their use, provided that such programs conform to health claims regulations if they characterize the relationship of a substance to a disease or health-related condition.

However, the agency points out that such programs, by virtue of their association with the articles of food in the retail store, generally constitute food labeling under section 201(m)(2) of the act and, as such, would be subject to regulation under section 403(r) of the act if a health claim is made. FDA does not agree that such programs should be exempt from these regulations. Consumers could be confused by differing claims on food labels and in these programs. For example, if under an in-store program, informational placards with a calcium/osteoporosis health claim were placed on a dairy case containing a wide variety of dairy products, some of the products contained in the case would likely be misbranded, as a number of dairy products exceed the disqualifying nutrient levels for fat and saturated fat or fail to meet other provisions of new § 101.14. Even those products that would otherwise qualify for a health claim would likely be misbranded if the placard claim itself did not conform to the provisions of new § 101.14 and part 101, subpart E.

The agency's regulations are designed to enable consumers to understand the significance of the consumption of the substance on the risk of disease within the context of the daily diet. Relevant in-store programs should be carefully crafted to convey such an understanding.

110. A number of comments took a position that one or more of the proposed provisions should not be established because they are subjects for regulatory review under the January 28, 1992, Presidential memo, "Reducing the Burden of Government Regulation." The comments asserted that these requirements are exercises in discretion by the agency rather than requirements mandated by Congress.

FDA advises that after considering these comments, it has concluded that none of the preliminary requirements reaches beyond the act to impose an unnecessary burden on manufacturers. As explained in the preamble of the proposal (56 FR 60537 at 60545 through 60547), each of these requirements is directly derived from existing provisions of the act. Even though these provisions are derived from the act, FDA has carefully reviewed each provision in accordance with the direction provided by the January 28, 1992, Presidential memo. FDA has carefully considered the benefits to society of these rules and concluded that the benefits clearly outweigh the expected costs (see the final RIA, published elsewhere in this issue of the **Federal Register**). Each provision of the rules has been fashioned to maximize net benefits to society. Further, the provisions have been crafted to clearly convey to the regulated community what is required of firms choosing to make health claims.

XIII. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), along with the food labeling proposals, and the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

XIV. Environmental Impact

The agency has previously considered the environmental effects of this rule as announced in the proposed rule (November 27, 1991 (56 FR 60537 at 60562)). At that time, FDA determined under 21 CFR 25.24(a)(8) and (a)(11) that this action was of a type that does not individually or cumulatively have a significant impact on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement was required.

Several comments on the proposed rules on health claims suggested that there would be significant adverse environmental effects from these rulemakings because it would cause large stocks of labels and labeled packaging materials to be discarded and require a great number of trees to be harvested to provide new labeling material. One comment estimated the number of label units from the dairy industry that would need to be discarded following publication of FDA's final rules on several food labeling actions, including this action. However, this comment did not: (1) Show how these estimates were derived, (2) identify what portion of the estimated amounts are attributable solely to this action, or (3) describe what impact the discarded labeling and packaging would have on the disposal of solid waste. Another comment questioned the appropriateness of requiring lengthy explanations on the labels of foods for which health claims are made because those requirements might result in extra packaging so that sufficient label space would be available for the required elements of the health claims. The comment said that this extra packaging might increase the burden on the environment but did not estimate the amount of extra packaging that might be needed or describe what impact this extra packaging would have on the environment.

According to section 10(a)(2) of the 1990 amendments, section 403(r) of the act does not apply to food labeled before May 8, 1993. Thus, all labels that are

applied to food prior to that date will not have to be destroyed. The comments contained no data with respect to labels that might remain that would fail to comply with the requirements of section 403(r)(1)(B) of the act. In the absence of such data, FDA has no basis on which to assess the validity of assertions that considerable label stocks will be destroyed and thereby determine the extent of any potential adverse environmental impact. Given the fact that section 10(a)(2) of the 1990 amendments provides an exemption for labeled products, and that FDA is authorizing various health claims elsewhere in this issue of the **Federal Register**, FDA believes that very little, if any, labeling will have to be discarded because of this final rule. Also, in its final rules, FDA has limited the required elements of many of the health claims compared to the elements that were proposed. Thus, FDA believes that the information required on a label when a health claim is made can be incorporated into the label without significantly increasing the amount of packaging required. Consequently, FDA concludes that the comments on the potential for adverse environmental effects do not affect the agency's previous determination that no significant impact on the human environment is expected and that an environmental impact statement is not required.

XV. Paperwork Reduction Act

In the **Federal Register** of February 14, 1992 (57 FR 5396), FDA announced that the agency had submitted to the Office of Management and Budget (OMB) for its review the collection of information requirements contained in the proposed rule (November 27, 1991, 56 FR 60537) that provided, in proposed § 100.70, for petitions regarding the use of health claims in conjunction with food labeling. Also in the February 1992 document, FDA published its estimated annual collection of information burden.

FDA considered over 6,000 written comments received in response to the aforementioned **Federal Register** documents and the oral presentations made at the public hearing on food labeling in developing this final rule. FDA has not been persuaded by the comments or any other relevant information to modify, in this final rule, the health claim petition requirements that it proposed last year. Thus, the agency's estimated annual reporting and recordkeeping burden from the health claim petition requirements contained in this final rule remains unchanged from that announced in February.

FDA has submitted copies of the final rule to OMB for its review of these reporting requirements.

List of Subjects

21 CFR Part 20

Confidential business information, Courts, Freedom of information, Government employees.

21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR parts 20 and 101 are amended as follows:

PART 20—PUBLIC INFORMATION

1. The authority citation for 21 CFR part 20 continues to read as follows:

Authority: Secs. 201–903 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321–393); secs. 301, 302, 303, 307, 310, 311, 351, 352, 354–360F, 361, 362, 1701–1706, 2101 of the Public Health Service Act (42 U.S.C. 241, 242, 242a, 242l, 242n, 243, 262, 263, 263b–263n, 264, 265, 300u–300u–5, 300aa–1); 5 U.S.C. 552; 18 U.S.C. 1905.

2. Section 20.100 is amended by revising the section heading and by adding new paragraph (c)(34) to read as follows:

§ 20.100 Applicability; cross-reference to other regulations.

* * * * *

(c) * * *

(34) Health claims petitions, in § 101.70 of this chapter.

PART 101—FOOD LABELING

3. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

4. Section 101.9 is amended by adding new paragraph (k)(1) to read as follows:

§ 101.9 Nutrition labeling of food.

* * * * *

(k) * * *

(1) That the food, because of the presence or absence of certain dietary properties, is adequate or effective in the prevention, cure, mitigation, or treatment of any disease or symptom. Information about the relationship of a dietary property to a disease or health-related condition may only be provided in conformance with the requirements of § 101.14 and part 101, subpart E.

* * * * *

5. New § 101.14 is added to read as follows:

§ 101.14 Health claims: general requirements.

(a) *Definitions.* For purposes of this section, the following definitions apply:

(1) *Health claim* means any claim made on the label or in labeling of a food, including a dietary supplement, that expressly or by implication, including "third party" references, written statements (e.g., a brand name including a term such as "heart"), symbols (e.g., a heart symbol), or vignettes, characterizes the relationship of any substance to a disease or health-related condition. Implied health claims include those statements, symbols, vignettes, or other forms of communication that suggest, within the context in which they are presented, that a relationship exists between the presence or level of a substance in the food and a disease or health-related condition.

(2) *Substance* means a specific food or component of food.

(3) *Nutritive value* means a value in sustaining human existence by such processes as promoting growth, replacing loss of essential nutrients, or providing energy.

(4) [Reserved]

(5) *Disqualifying nutrient levels* means the levels of total fat, saturated fat, cholesterol, or sodium in a food above which the food will be disqualified from making a health claim. These levels are 13.0 grams (g) of fat, 4.0 g of saturated fat, 60 milligrams (mg) of cholesterol, or 480 mg of sodium, per reference amount customarily consumed, per label serving size, and, only for foods with reference amounts customarily consumed of 30 g or less or 2 tablespoons or less, per 50 g. For dehydrated foods that must have water added to them prior to typical consumption, the per 50-g criterion refers to the as prepared form. Any one of the levels, on a per reference amount customarily consumed, a per label serving size or, when applicable, a per 50 g basis, will disqualify a food from making a health claim unless an exception is provided in subpart E of this part, except that:

(i) The levels for a meal product as defined in § 101.13(l) are 26.0 g of fat, 8.0 g of saturated fat, 120 mg of cholesterol, or 960 mg of sodium per label serving size, and

(ii) The levels for a main dish product as defined in § 101.13(m) are 19.5 g of fat, 6.0 g of saturated fat, 90 mg of cholesterol, or 720 mg of sodium per label serving size.

(6) *Disease or health-related condition* means damage to an organ, part, structure, or system of the body such that it does not function properly (e.g., cardiovascular disease), or a state of health leading to such dysfunctioning (e.g., hypertension); except that diseases resulting from essential nutrient deficiencies (e.g., scurvy, pellagra) are not included in this definition (claims pertaining to such diseases are thereby not subject to § 101.14 or § 101.70).

(b) *Eligibility.* For a substance to be eligible for a health claim:

(1) The substance must be associated with a disease or health-related condition for which the general U.S. population, or an identified U.S. population subgroup (e.g., the elderly) is at risk, or, alternatively, the petition submitted by the proponent of the claim otherwise explains the prevalence of the disease or health-related condition in the U.S. population and the relevance of the claim in the context of the total daily diet and satisfies the other requirements of this section.

(2) If the substance is to be consumed as a component of a conventional food at decreased dietary levels, the substance must be a nutrient listed in 21 U.S.C. 343(q)(1)(C) or (q)(1)(D), or one that the Food and Drug Administration (FDA) has required to be included in the label or labeling under 21 U.S.C. 343(q)(2)(A); or

(3) If the substance is to be consumed at other than decreased dietary levels:

(i) The substance must contribute taste, aroma, or nutritive value, or any technical effect listed in § 170.3(o) of this chapter, to the food and must retain that attribute when consumed at levels that are necessary to justify a claim; and

(ii) The substance must be a food or a food ingredient or a component of a food ingredient whose use at the levels necessary to justify a claim has been demonstrated by the proponent of the claim, to FDA's satisfaction, to be safe and lawful under the applicable food safety provisions of the Federal Food, Drug, and Cosmetic Act.

(c) *Validity requirement.* FDA will promulgate regulations authorizing a health claim only when it determines, based on the totality of publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), that there is significant scientific agreement, among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

(d) *General health claim labeling requirements.* (1) When FDA determines that a health claim meets the validity requirements of paragraph (c) of this

section, FDA will propose a regulation in subpart E of this part to authorize the use of that claim. If the claim pertains to a substance not provided for in § 101.9, FDA will propose amending that regulation to include declaration of the substance.

(2) When FDA has adopted a regulation in subpart E of this part providing for a health claim, firms may make claims based on the regulation in subpart E of this part, provided that:

(i) All label or labeling statements about the substance-disease relationship that is the subject of the claim are based on, and consistent with, the conclusions set forth in the regulations in subpart E of this part;

(ii) The claim is limited to describing the value that ingestion (or reduced ingestion) of the substance, as part of a total dietary pattern, may have on a particular disease or health-related condition;

(iii) The claim is complete, truthful, and not misleading. Where factors other than dietary intake of the substance affect the relationship between the substance and the disease or health-related condition, such factors may be required to be addressed in the claim by a specific regulation in subpart E of this part;

(iv) All information required to be included in the claim appears in one place without other intervening material, except that the principal display panel of the label or labeling may bear the reference statement, "See ———— for information about the relationship between ———— and ————," with the blanks filled in with the location of the labeling containing the health claim, the name of the substance, and the disease or health-related condition (e.g., "See attached pamphlet for information about calcium and osteoporosis"), with the entire claim appearing elsewhere on the other labeling, Provided that, where any graphic material (e.g., a heart symbol) constituting an explicit or implied health claim appears on the label or labeling, the reference statement or the complete claim shall appear in immediate proximity to such graphic material;

(v) The claim enables the public to comprehend the information provided and to understand the relative significance of such information in the context of a total daily diet; and

(vi) If the claim is about the effects of consuming the substance at decreased dietary levels, the level of the substance in the food is sufficiently low to justify the claim. To meet this requirement, if a definition for use of the term "low" has been established for that substance under this part, the substance must be present at a level that meets the requirements for use of that term, unless a specific alternative level has been established for the substance in subpart E of this part. If no definition for "low" has been established, the level of the substance must meet the level established in the regulation authorizing the claim; or

(vii) If the claim is about the effects of consuming the substance at other than decreased dietary levels, the level of the substance is sufficiently high and in an appropriate form to justify the claim. To meet this requirement, if a definition for use of the term "high" for that substance has been established under this part, the substance must be present at a level that meets the requirements for use of that term, unless a specific alternative level has been established for the substance in subpart E of this part. If no definition for "high" has been established (e.g., where the claim pertains to a food either as a whole food or as an ingredient in another food), the claim must specify the daily dietary intake necessary to achieve the claimed effect, as established in the regulation authorizing the claim; *Provided* that:

(A) Where the food that bears the claim meets the requirements of paragraphs (d)(2)(vi) or (d)(2)(vii) of this section based on its reference amount customarily consumed, and the labeled serving size differs from that amount, the claim shall be followed by a statement explaining that the claim is based on the reference amount rather than the labeled serving size (e.g., "Diets low in salt and sodium may help lower blood pressure in many people. A serving of ———— ounces of this product conforms to such a diet.").

(B) Where the food that bears the claim is sold in a restaurant (except if the claim is made on a menu) or in other establishments in which food that is ready for human consumption is sold, the food can meet the requirements of paragraphs (d)(2)(vi) or (d)(2)(vii) of this section if the firm that sells the food has a reasonable basis on which to believe that the food that bears the claim meets the requirements of paragraphs (d)(2)(vi) and (d)(2)(vii) of this section and providing that basis upon request.

(3) Nutrition labeling shall be provided in the label or labeling of any food for which a health claim is made in accordance with § 101.9 or, for restaurant foods, in accordance with § 101.10.

(e) *Prohibited health claims.* No expressed or implied health claim may be made on the label or in labeling for a food unless:

(1) The claim is specifically provided for in subpart E of this part; and

(2) The claim conforms to all general provisions of this section as well as to all specific provisions in the appropriate section of subpart E of this part;

(3) None of the disqualifying levels identified in paragraph (a)(5) of this section is exceeded in the food, unless specific alternative levels have been established for the substance in subpart E of this part; or unless FDA has permitted a claim despite the fact that a disqualifying level of a nutrient is present in the food based on a finding that such a claim will assist consumers in maintaining healthy dietary practices, and, in accordance with the regulation in subpart E of this part that makes such a finding, the label bears a referral statement that complies with § 101.13(h), highlighting the nutrient that exceeds the disqualifying level;

(4) Except as provided in paragraph (e)(3) of this section, no substance is present at an inappropriate level as determined in the specific provision authorizing the claim in subpart E of this part;

(5) The label does not represent or purport that the food is for infants and toddlers less than 2 years of age except if the claim is specifically provided for in subpart E of this part; and

(6) Except for dietary supplements not in conventional food form, the food contains 10 percent or more of the Reference Daily Intake or the Daily Reference Value for vitamin A, vitamin C, iron, calcium, protein, or fiber per reference amount customarily consumed prior to any nutrient addition.

(f) The requirements of this section do not apply to:

(1) Infant formulas subject to section 412(h) of the Federal Food, Drug, and Cosmetic Act, and

(2) Medical foods defined by section 5(b) of the Orphan Drug Act.

(g) *Applicability.* The requirements of this section apply to foods intended for human consumption that are offered for sale.

6. Subpart E, consisting of §§ 101.70 and 101.71, is added to read as follows:

Subpart E—Specific Requirements for Health Claims

Sec.

Subpart E—Specific Requirements for Health Claims

§ 101.70 Petitions for health claims.

(a) Any interested person may petition the Food and Drug

Administration (FDA) to issue a regulation regarding a health claim. An original and one copy of the petition shall be submitted, or the petitioner may submit an original and a computer readable disk containing the petition. Contents of the disk should be in a standard format, such as ASCII format. (Petitioners interested in submitting a disk should contact the Center for Food Safety and Applied Nutrition for details.) If any part of the material submitted is in a foreign language, it shall be accompanied by an accurate and complete English translation. The petition shall state the petitioner's post office address to which any correspondence required by section 403 of the Federal Food, Drug, and Cosmetic Act may be sent.

(b) Pertinent information may be incorporated in, and will be considered as part of, a petition on the basis of specific reference to such information submitted to and retained in the files of FDA. Such information may include any findings, along with the basis of the findings, of an outside panel with expertise in the subject area. Any reference to published information shall be accompanied by reprints, or easily readable copies of such information.

(c) If nonclinical laboratory studies are included in a petition, the petition shall include, with respect to each nonclinical study contained in the petition, either a statement that the study has been conducted in compliance with the good laboratory practice regulations as set forth in part 58 of this chapter, or, if any such study was not conducted in compliance with such regulations, a brief statement of the reason for the noncompliance.

(d) If clinical or other human investigations are included in a petition, the petition shall include a statement that they were either conducted in compliance with the requirements for institutional review set forth in part 56 of this chapter, or were not subject to such requirements in accordance with § 56.104 or § 56.105, and a statement that they were conducted in compliance with the requirements for informed consent set forth in part 50 of this chapter.

(e) All data and information in a health claim petition are available for public disclosure after the notice of filing of petition is issued to the petitioner, except that clinical investigation reports, adverse reaction reports, product experience reports, consumer complaints, and other similar data and information shall only be available after deletion of:

(1) Names and any information that would identify the person using the product.

(2) Names and any information that would identify any third party involved with the report, such as a physician or hospital or other institution.

(f) Petitions for a health claim shall include the following data and be submitted in the following form:

———————

(Date)

Name of petitioner ———————

Post office address ———————

Subject of the petition ———————

Food and Drug Administration,
Regulatory Affairs Staff (HFF–204),
Office of Nutrition and Food Sciences,
200 C St. SW.,
Washington, DC 20204,

The undersigned,

——————————— submits this petition pursuant to section 403(r)(4) or (r)(5)(D) of the Federal Food, Drug, and Cosmetic Act with respect to (statement of the substance and its health claim).

Attached hereto, in quadruplicate, and constituting a part of this petition, are the following:

A. Preliminary requirements. A complete explanation of how the substance conforms to the requirements of § 101.14(b) (21 CFR 101.14(b)). For petitions where the subject substance is a food ingredient or a component of a food ingredient, the petitioner should compile a comprehensive list of the specific ingredients that will be added to the food to supply the substance in the food bearing the health claim. For each such ingredient listed, the petitioner should state how the ingredient complies with the requirements of § 101.14(b)(3)(ii), e.g., that its use is generally recognized as safe (GRAS), listed as a food additive, or authorized by a prior sanction issued by the agency, and what the basis is for the GRAS claim, the food additive status, or prior sanctioned status.

B. Summary of scientific data. The summary of scientific data provides the basis upon which authorizing a health claim can be justified as providing the health benefit. The summary must establish that, based on the totality of publicly available scientific evidence (including evidence from well-designed studies conducted in a manner which is consistent with generally recognized scientific procedures and principles), there is significant scientific agreement among experts qualified by scientific training and experience to evaluate such claims, that the claim is supported by such evidence.

The summary shall state what public health benefit will derive from use of the claim as proposed. If the claim is intended for a specific group within the population, the summary shall specifically address nutritional needs of such group and shall include scientific data showing how the claim is likely to assist in meeting such needs.

The summary shall concentrate on the findings of appropriate review articles, National Institutes of Health consensus development conferences, and other appropriate resource materials. Issues addressed in the summary shall include answers to such questions as:

1. Is there an optimum level of the particular substance to be consumed beyond which no benefit would be expected?

2. Is there any level at which an adverse effect from the substance or from foods containing the substance occurs for any segment of the population?

3. Are there certain populations that must receive special consideration?

4. What other nutritional or health factors (both positive and negative) are important to consider when consuming the substance?

In addition, the summary of scientific data shall include a detailed analysis of the potential effect of the use of the proposed claim on food consumption, specifically any change due to significant alterations in eating habits and corresponding changes in nutrient intake resulting from such changes in food consumption. The latter item shall specifically address the effect on the intake of nutrients that have beneficial and negative consequences in the total diet.

If the claim is intended for a significant subpopulation within the general U.S. population, the analysis shall specifically address the dietary practices of such group, and shall include data sufficient to demonstrate that the dietary analysis is representative of such group (e.g., adolescents or the elderly).

If appropriate, the petition shall explain the prevalence of the disease or health-related condition in the U.S. population and the relevance of the claim in the context of the total daily diet.

Also, the summary shall demonstrate that the substance that is the subject of the proposed claim conforms to the definition of the term "substance" in § 101.14(a)(2).

C. Analytical data that show the amount of the substance that is present in representative foods that would be candidates to bear the claim should be obtained from representative samples using methods from the Association of Official Analytical Chemists (AOAC), where available. If no AOAC method is

available, the petitioner shall submit the assay method used and data establishing the validity of the method for assaying the substance in food. The validation data should include a statistical analysis of the analytical and product variability.

D. Model health claim. One or more model health claims that represent label statements that may be used on a food label or in labeling for a food to characterize the relationship between the substance in a food to a disease or health-related condition that is justified by the summary of scientific data provided in section C of the petition. The model health claim shall include:

1. A brief capsulized statement of the relevant conclusions of the summary, and

2. A statement of how this substance helps the consumer to attain a total dietary pattern or goal associated with the health benefit that is provided.

E. The petition shall include the following attachments:

1. Copies of any computer literature searches done by the petitioner (e.g., Medline).

2. Copies of articles cited in the literature searches and other information as follows:

a. All information relied upon for the support of the health claim, including copies of publications or other information cited in review articles and used to perform meta-analyses.

b. All information concerning adverse consequences to any segment of the population (e.g., sensitivity to the substance).

c. All information pertaining to the U.S. population.

F. The petitioner is required to submit either a claim for categorical exclusion under § 25.24 of this chapter or an environmental assessment under § 25.31 of this chapter.

Yours very truly,

Petitioner ————————

By ————————

(Indicate authority)

(g) The data specified under the several lettered headings should be submitted on separate pages or sets of pages, suitably identified. If such data have already been submitted with an earlier application from the petitioner or any other final petition, the present petition may incorporate it by specific reference to the earlier petition.

(h) The petition shall include a statement signed by the person responsible for the petition that, to the best of his/her knowledge, it is a representative and balanced submission that includes unfavorable information as well as favorable information, known to him/her to be pertinent to the evaluation of the proposed health claim.

(i) The petition shall be signed by the petitioner or by his/her attorney or agent, or (if a corporation) by an authorized official.

(j) *Agency action on the petition.* (1) Within 15 days of receipt of the petition, the petitioner will be notified by letter of the date on which the petition was received. Such notice will inform the petitioner that the petition is undergoing agency review and that the petitioner will subsequently be notified of the agency's decision to file for comprehensive review or deny the petition.

(2) Within 100 days of the date of receipt of the petition, FDA will notify the petitioner by letter that the petition has either been filed for comprehensive review or denied. The agency will deny a petition without reviewing the information contained in B. *Summary of Scientific Data* if the information in A. *Preliminary Requirements* is inadequate in explaining how the substance conforms to the requirements of § 101.14(b). If the petition is denied, the notification will state the reasons therefor, including justification of the rejection of any report from an authoritative scientific body of the U.S. Government. If filed, the date of the notification letter becomes the date of filing for the purposes of this regulation. A petition that has been denied without filing will not be made available to the public. A filed petition will be available to the public to the extent provided under paragraph (e) of this section.

(3) Within 90 days of the date of filing, FDA will by letter of notification to the petitioner:

(i) Deny the petition, or

(ii) Inform the petitioner that a proposed regulation to provide for the requested use of the health claim will be published in the **Federal Register**. If the petition is denied, the notification will state the reasons therefor, including justification for the rejection of any report from an authoritative scientific body of the U.S. Government. FDA will publish the proposal to amend the regulations to provide for the requested use of the health claim in the **Federal Register** within 90 days of the date of filing. The proposal will also announce the availability of the petition for public review.

§ 101.71 Health claims: claims not authorized.

In response to the Nutrition Labeling and Education Act of 1990, FDA has reviewed the evidence on the following topics that Congress specifically asked FDA to evaluate and has concluded that there is not a sufficient basis for claims about the following:

Dated: December 17, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

21 CFR Part 101

[Docket No. 91N–0098]

RIN 0905–AD08

Food Labeling: Health Claims and Label Statements; Dietary Fiber and Cancer

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision not to authorize the use on the label or labeling of foods of health claims relating to an association between dietary fiber and cancer. However, FDA is authorizing a health claim relating diets low in fat and high in fiber-containing grain products, fruits, and vegetables to a reduced risk of cancer. This action is in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims, and was developed in accordance with the final rule on general requirements for health claims, published elsewhere in this issue of the **Federal Register**.

Based on the totality of the publicly available scientific evidence, including recently available evidence, the agency has concluded that there is not significant scientific agreement among qualified experts that a claim relating dietary fiber to reduced risk of cancer is supported. The publicly available evidence does indicate, however, that diets low in fat and rich in fiber-containing grain products, fruits, and vegetables are associated with a decreased risk of several types of cancer, and there is significant scientific agreement that the evidence supports this association. The evidence is not sufficient to fully explain the role of total dietary fiber, fiber components, and the multiple nutrients and other substances contained in these foods in reducing cancer risk.

EFFECTIVE DATE: May 8, 1993.

FOR FURTHER INFORMATION CONTACT: Joyce J. Saltsman, Center for Food Safety and Applied Nutrition (HFS–165), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–5916.

SUPPLEMENTARY INFORMATION:

I. Background

In the **Federal Register** of November 27, 1991 (56 FR 60566), FDA proposed to deny the use of health claims relating dietary fiber to the risk of cancer on food labeling. The proposed rule was issued in response to provisions of the 1990 amendments (Pub. L. 101–535) that bear on health claims and in accordance with the proposed general requirements for health claims for food (56 FR 60537). As amended in 1990, the Federal Food, Drug, and Cosmetic Act (the act) provides that a food is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition unless the claim is made in accordance with section 403(r)(3) or 403(r)(5)(D) of the act (21 U.S.C. 343(r)(3) or 343(r)(5)(D)).

Congress enacted the health claims provisions of the 1990 amendments (Pub. L. 101–535) to help U.S. consumers maintain good health through appropriate dietary patterns and to protect consumers from unfounded health claims. Section 3(b)(1)(A) of the 1990 amendments specifically requires the agency to determine whether claims respecting 10 nutrient/disease relationships meet the requirements of section 403(r)(3) or 403(r)(5)(D) of the act. The relationship between dietary fiber and cancer is one of the claims required to be evaluated. In carrying out this inquiry, FDA limited its scientific review to the area for which the strongest scientific evidence and agreement existed: Dietary fiber and cancers of the colon and rectum (colorectal cancers).

FDA published a notice in the **Federal Register** of March 28, 1991 (56 FR 12932), requesting scientific data and information on the 10 specific topic areas identified in the 1990 amendments, including dietary fiber and cancer. Relevant scientific studies and data received in response to this request were considered as part of the agency's review of the scientific literature on dietary fiber and cancer, and they were included in the proposed rule. Comments received in response to the notice and not specifically addressed in the proposed rule are summarized and addressed below.

In the proposed rule (56 FR 60566), FDA requested written comments on its tentative determination not to authorize a health claim for dietary fiber and cancer. FDA also requested comments on the following issues: (1) Should the agency permit the label or labeling of certain foods to state, for example, that diets high in fruit, vegetables, and whole grains are associated with a reduced risk of certain forms of cancer and cardiovascular disease?; (2) If such a statement were permitted, what criteria should be used to identify eligible foods? For example, should such statements be limited to fresh fruit, vegetables, and milled whole grains; or should processed foods derived from these products also be included?; (3) What measures should the agency adopt to assure that consumers are not misled as to the benefit of consuming a specific product?; (4) Does FDA have the authority to allow health claims for foods as well as nutrients?; (5) What qualifying and disqualifying criteria should be used to determine eligibility for a claim, and what methods or criteria should be used for regulatory monitoring and compliance?; (6) What criteria could be used to develop a health claim for foods that would provide truthful and not misleading messages to consumers that changes in dietary patterns are related to reductions in cancer risk (56 FR at 60577)?

In addition, FDA held public hearings on January 30 and 31, 1992, on all aspects of the proposed rules published in response to the 1990 amendments.

II. Summary of Comments and the Agency's Responses

The agency received approximately 100 comments (including those from the March 28, 1991, request) in response to its proposed rule on health claims for dietary fiber and cancer. Comments were received from consumers, consumer advocacy groups, state health departments, organizations of health professionals, the food industry, and Government agencies.

The agency has summarized and addressed the issues raised in these comments below. Data submitted in scientific articles that were not reviewed in the proposed rule or in any of the Federal Government consensus documents or Life Sciences Research Office (LSRO) reports are discussed in the agency's review of recent scientific evidence in section III of this document. A number of the comments received were more appropriately addressed in other documents, and these comments were forwarded to the appropriate docket for response.

A. General Comments

1. Several comments stated that there is sufficient scientific evidence to support a health claim that diets high in dietary fiber can reduce the risk of colon cancer. These comments maintained that it is well known that population groups who consume high-fiber diets have a lower incidence of cancer, and these comments cited the strength of international correlational data on per capita availability of fiber and risk of colon cancer. Other comments stated that FDA should allow a health claim regarding dietary fiber and cancer

because cancer is a major public health problem, and it is important for consumers to be well informed. Several comments stated that FDA failed to consider the rapid pace of scientific advances linking nutritional substances to the maintenance of long-term health and disease prevention.

FDA agrees that cancer is a significant public health problem and is a significant cause of death. Colorectal cancers are the second and third leading causes of cancer deaths in the United States for men and women, respectively (Ref. 46). As FDA described in its proposed rule (56 FR 60566), numerous human and animal studies have examined the possible role of dietary fiber intake in reducing the risk of developing colon cancer. Most correlational studies and many (but not all) case-control studies show that diets high in fiber-containing foods (whole grains, fruits, and vegetables) are associated with a reduced risk of colorectal cancer. Prospective epidemiologic studies are few in number and give mixed results. Animal studies indicate that certain types of dietary fiber, but not others, may be important in modulating the effects of chemical carcinogens.

FDA agrees that there is substantial evidence that diets high in fiber-rich foods, including whole grains, fruits, and vegetables, are associated with reduced risk of colorectal cancer. These diets differ, however, in levels of many nutrients and in types of dietary fiber, making it difficult to attribute the observed diet-disease relationship to a single nutrient. Overall, the available data are not sufficient to demonstrate that it is the total dietary fiber, or a specific fiber component, or specific vitamins and minerals (singly or interactively) that are related to reduction of cancer risk.

The agency disagrees with the comments that assert that international correlational data on fiber per capita availability and risk of colon cancer are sufficient to justify a health claim regarding dietary fiber and cancer. While the correlation coefficients of such studies are often large, these studies are very weak in controlling for confounding variables. Many of the countries with low incidences of colon cancer are undeveloped nations that differ in many ways from Western countries (for example, in prevalence of obesity, environmental pollution, genetic susceptibility, parasitic diseases, etc.). None of the international correlation studies reports actual food consumption; instead, each attributes consumption of fiber from averages of food disappearance. This approach does not account for food disappearance through loss or wastage (peeling, etc.) or for differing dietary habits among various socioeconomic groups within a single country. Thus, in its proposed rule, FDA tentatively found that a basis did not exist on which to authorize a health claim relating to an association between ingestion of dietary fiber and risk of cancer. In this final rule, FDA is not authorizing a dietary fiber and cancer health claim because, based on the agency's review of the scientific evidence, including scientific literature that became publicly available after the proposal's publication, and review of data in comments, the agency has concluded that the evidence is not sufficiently conclusive or specific for dietary fiber per se to justify such a health claim. The agency has concluded, however, that there is sufficient evidence to support a claim relating the ingestion of fruits, vegetables, and whole grain products to reduced risk of some cancers. These foods are also generally low in fat and are good sources of dietary fiber.

2. Several comments stated that FDA did not follow the congressional mandate to consider whether there is significant scientific agreement supporting specific health claims. The comments argued that the agency should have first identified the range of specific health claims that could be made about dietary fiber and cancer and then examined the scientific support for each claim. A related comment asserted that FDA's evaluation criteria for specific scientific studies were based on a fundamental misapprehension of its role under the 1990 amendments. The comments stated that FDA's proper role is to search the science for significant agreement, not decide the validity of studies.

FDA disagrees with these comments. The 1990 amendments did not instruct the agency to identify the wide range of health claims that might be made with respect to the 10 topics identified and then to evaluate all published literature relevant to the claims. Rather, the 1990 amendments instructed the agency to determine whether claims respecting the 10 areas, including "dietary fiber and cancer," meet the requirements of section 403(r)(3) or 403(r)(5)(D) of the act. The agency interpreted this directive in a straightforward and logical way. Indeed, FDA's chosen approach was necessary if the agency hoped to accomplish the congressional mandate within the prescribed timeframe and with its limited resources. Thus, FDA, in its proposed rule (56 FR 60566), focused its scientific review on those aspects of the dietary fiber and cancer relationship for which the strongest scientific evidence exists: dietary fiber and colorectal cancer.

The agency developed its proposed rule regarding dietary fiber and cancer in conformity with the standards mandated by the 1990 amendments. FDA's role is to evaluate the totality of the publicly available scientific evidence and to assess whether there is significant scientific agreement among qualified experts that the available evidence supports the proposed claim. This evaluation necessarily involves an assessment of the validity of studies rather than merely a search for scientific agreement.

3. Several comments stated that FDA rejected health claims for dietary fiber and cancer because of rigid application of a scientific standard higher than that mandated by the 1990 amendments and that this rejection will have unfortunate public health consequences because valuable health-related information will not be transmitted to the American population.

FDA does not agree that it has applied a scientific standard higher than the one set out in section 403(r)(3)(B)(i) of the act. As required by the statute, FDA evaluated possible health claims for dietary fiber and cancer by inquiring whether, based on the totality of publicly available scientific evidence (including evidence from well-designed studies), there is significant scientific agreement among qualified experts that the claim is supported. FDA is codifying the scientific standard of section 403(r)(3)(B)(i) of the act at 21 CFR 101.14(c) in the final rule on general requirements for health claims, which is published elsewhere in this **Federal Register**.

4. Several comments stated that FDA used different criteria to assess the relationship between dietary lipids and cancer and the relationship between dietary fiber and cancer.

FDA disagrees with this comment. In reviewing the scientific literature, FDA followed the standard mandated by the 1990 amendments. However, the strength and consistency of the data in these two areas led the agency to reach two different conclusions about permitting health claims.

Assessments of the relevant scientific data, in Federal Government reports and other authoritative documents, have consistently concluded that dietary fat contributes to the risk of cancer at certain sites. In developing its proposed rule on this relationship (56 FR 60764), the agency found that new evidence was consistent with these earlier conclusions. Based on the totality of the evidence, FDA concluded that diets low

in total fat are associated with a reduced risk of some types of cancer.

In contrast, authoritative scientific documents, including Federal Government reports, have concluded that a number of components of diets rich in fruits, vegetables, and grain products contribute to their beneficial effect on cancer. For example, in its summary on dietary fiber and cancer in the National Academy of Sciences' report "Diet and Health: Implications for Reducing Chronic Disease Risk"("Diet and Health") (Ref. 30), the Committee on Diet and Health stated that "[E]ven where the evidence is strongest, it is not possible to adequately separate the effects of fiber from those of other components of the diet (e.g., total calories, fats, vitamins, minerals, and nonnutritive constituents of fruits and vegetables) and nondietary factors (e.g., socioeconomic status)." Similarly, "Healthy People 2000: National Health Promotion and Disease Prevention Objectives" ("Healthy People 2000") (Ref. 46) notes that recommendations from the National Cancer Institute (Refs. 53 through 55), the Surgeon General's Report, the National Academy of Sciences' "Diet and Health," and "Nutrition and Your Health: Dietary Guidelines for Americans" support increased consumption of vegetables, fruits, and whole grains and cereals (Refs. 47, 30, and 45, respectively). In developing its proposed rule on dietary fiber and cancer, the agency found that new evidence did not alter these earlier conclusions. Rather, the agency found that the available scientific evidence was not sufficiently conclusive or specific for fiber per se to justify a health claim relating intake of dietary fiber alone to reduced risk of cancer.

5. Several comments stated that there were disparities in the agency's treatment of confounders, the weight given clinical studies, and emphasis on animal studies between the proposed rules on fat and cancer and on fiber and cancer. One comment stated that FDA criticized several of the fiber and cancer studies because it was not possible to separate the effects of dietary fiber from the effects of a reduced fat intake, but that the agency did not make this criticism of the fat and cancer studies.

FDA disagrees with these comments. In the fiber and cancer studies referred to in the comment, dietary fat was decreased and dietary fiber was increased; therefore, the effects could not be separated. In the majority of the fat and cancer studies, however, dietary fat was decreased and dietary fiber remained the same. Therefore, the reduction in risk of cancer observed in these studies could not have been due to an increased fiber intake.

FDA also disagrees that it relied excessively on animal studies in the fat and cancer proposal. As FDA noted in the proposed regulation on dietary fiber and colon cancer (56 FR 60566), in general, animal studies on fiber show no consistent protective effect. In contrast, animal studies on fat and cancer, taken as a whole, support a promoting effect of fat on carcinogenesis at several sites independent of the effect of energy intake. Human studies on fat are also generally supportive of a promoting effect of fat on carcinogenesis with respect to some types of cancer. The evidence on the relation between fat and cancer is further discussed in the document "Dietary Lipids and Cancer" published elsewhere in this issue of the **Federal Register**.

6. One comment stated that there are several clinical studies on fiber and few on fat and, therefore, the health claim on fiber and cancer should be approved.

FDA disagrees with this comment. The available clinical studies on fiber investigate its relationship to precursor lesions such as polyps, dysplasias, and abnormal cell morphology of the colonic epithelium, rather than to cancer itself. These studies are difficult to interpret, because at this time the actual risk factors for colorectal cancer are still incompletely understood. Moreover, it is not known how valid are markers such as secondary bile acid concentration, fecal mutagenicity, fecal weight, fecal deoxycholic acid, and activity of fecal bacterial enzymes as surrogates for the disease of colon cancer. Additional studies are needed to establish which, if any, of these factors affect the development of human colon cancer.

7. Some comments stated that FDA failed to justify its rejection of authoritative Federal Government reports (specifically, National Cancer Institute (NCI) recommendations containing the word "fiber").

FDA does not agree that, in developing its proposed rule regarding fiber and cancer, it rejected conclusions of Federal Government reports. Some comments, by citing only those portions of dietary recommendations that include the word "fiber," seek to attribute the protective effects of diets high in fruits, vegetables, and grain products to fiber per se. FDA believes that this emphasis distorts the meaning of sound dietary recommendations by failing to acknowledge the important contributions to reduced risk of disease of the wide variety of nutrients and non-nutritive substances present in diets high in fruits, vegetables, and grain products. Such an emphasis also focuses attention away from changes in overall dietary patterns and their potential contribution to reducing risk of chronic diseases.

To date, neither the Surgeon General's Report on "Nutrition and Health" (Ref. 47), the National Academy of Sciences' "Diet and Health" (Ref. 30), nor DHHS' "Healthy People 2000" (Ref. 46) has found the scientific evidence strong enough to attribute the protective effects against cancer of dietary patterns high in fruits, vegetables, and grain products solely to the fiber content of such diets. The recommendations in the Surgeon General's Report (the Report) include increased consumption of whole grain foods and cereal products, vegetables (including dried beans and peas) and fruits (Ref. 47). The Report states, "While inconclusive, some evidence also suggests that an overall increase in intake of foods high in fiber might decrease the risk for colon cancer. Among several unresolved issues is the role of various types of fiber, which differ in their effects on water-holding capacity, viscosity, bacterial fermentation, and intestinal transit time."

Similarly, the National Research Council's "Diet and Health" recommends, "Every day eat five or more servings of a combination of vegetables and fruits, especially green and yellow vegetables and citrus fruits. Also, increase intake of starches and other complex carbohydrates by eating six or more daily servings of a combination of breads, cereals, and legumes." (Ref. 30). The summary concludes:

> Studies in various parts of the world indicate that people who habitually consume a diet high in plant foods have low risks of atherosclerotic cardiovascular diseases, probably largely because such diets are usually low in animal fat and cholesterol. Some constituents of plant foods, e.g., soluble fiber and vegetable protein, may also contribute—to a lesser extent—to the lower risk of atherosclerotic cardiovascular diseases. The mechanism for the link between frequent consumption of vegetables and fruits, especially green and yellow vegetables and citrus fruits, and decreased susceptibility to cancers of the lung, stomach, and large intestine is not well understood because the responsible agents in these foods and the mechanisms for their protective effect have not been fully determined. However, there is strong evidence that a low intake of carotenoids, which are present in green and yellow vegetables, contributes to an increased risk of lung cancer. Fruits and vegetables also contain high levels of fiber, but there is no conclusive evidence that the dietary fiber itself, rather than other nutritive and non-nutritive components of these foods, exerts a protective effect against these

cancers. The Committee does not recommend the use of fiber supplements.

"Healthy People 2000" (Ref. 46) notes that recommendations from the National Cancer Institute, the Surgeon General's Report, the National Academy of Sciences' "Diet and Health," and "Dietary Guidelines for Americans" support increased consumption of vegetables, fruits, and whole grain breads and cereals (Refs. 47, 30, and 45, respectively).

The agency's decision to prohibit the use on the label or labeling of foods of health claims relating intake of dietary fiber to decreased risk of cancer is consistent with the conclusions of Federal Government and other authoritative reports. Moreover, the agency's determination in this final rule to authorize a health claim relating diets low in fat and high in fiber-containing grains, fruits, and vegetables to a reduced cancer risk is quite consistent with the conclusions of these reports.

8. Several comments criticized the agency for starting its review of the scientific literature with consensus documents and Government reports rather than conducting its own review of the older literature and, secondly, for focusing on the scientific evidence concerning the relationship between dietary fiber and colorectal cancer rather than on that between insoluble fiber and colorectal cancer.

FDA disagrees with these comments. In evaluating the publicly available evidence for each of the 10 health claim topics, FDA reviewed the evidence and conclusions reached in several Federal Government documents and in other reports from recognized scientific bodies (56 FR 60566). These authoritative documents represent comprehensive reviews and evaluations of the literature available at the time of their publication (generally from 1987 to 1989) and represent scientific consensus at that time. Although the reports may not have referenced a particular study described in the comment, it is improbable that the studies reviewed in the reports missed an important effect.

In preparing its proposed rule, FDA updated these reports by independently reviewing subsequently published studies. In addition, to ensure that its review of relevant evidence was complete, FDA requested in the **Federal Register** of March 28, 1991 (56 FR 12932), scientific data and information on the 10 specific topic areas. The agency also reviewed and considered comments received in response to that **Federal Register** notice in developing its proposed rules. In reviewing the totality of the publicly available evidence, FDA considered studies that addressed the relationship between dietary fiber and colorectal cancer and those that addressed the relationship between insoluble fiber and colorectal cancer.

9. One comment questioned the motivation behind the agency's tentative rejection of health claims for fiber and cancer. The comment stated that the National Cancer Institute did not endorse health claims on dietary supplements, and stated that health claims for fiber should not be prohibited based on a concern that dietary supplements will be able to bear claims. Comments from supplement manufacturers asserted that, if health claims are permitted on foods containing fiber, then fiber supplements should also be permitted to carry claims. The comment argued that there is no difference between fiber in foods and fiber in supplements and that all fiber supplements are safe, although data were not included to substantiate such a claim.

FDA does not agree that its motivation for rejecting health claims associating dietary fiber and reduced cancer risk was to prevent supplement manufacturers from making such claims. As the agency's proposal makes clear, FDA tentatively decided to deny health claims for dietary fiber and cancer because the currently available scientific evidence is not sufficiently conclusive or specific for fiber per se to justify such a claim, not because the agency wishes to preclude use of such a claim on dietary supplements.

B. Comments Regarding a Relationship Between Dietary Fiber and Cancer

10. Several comments stated that health claims for insoluble fiber, particularly grain fiber, should be allowed. Another comment stated that wheat bran and related products that affect gastrointestinal transit time and fecal weight may help prevent colon cancer when consumed with a diet low in saturated fat and high in plant foods. This comment argued that the fact that animal studies show a protective effect in the colon by fibers with bulking properties is more important than understanding the underlying mechanism. The comment stated further that only specific fibers shown in animal studies to be protective, such as whole grain wheat, should be permitted to carry label claims.

FDA disagrees with these comments. Animal data are not consistent in showing a protective effect for insoluble dietary fiber. Indeed, corn bran, a predominantly insoluble fiber source (78 percent neutral detergent fiber), has been shown in three animal studies to enhance chemical carcinogenesis in rodents (Refs. 59, 60, and 61). While it is true that animal feeding studies using wheat bran are the most consistent in showing protective effects, animal data cannot be applied directly to humans. Taken together, the evidence for a significant role of wheat fiber in humans is still controversial. The number of human studies breaking fiber down by type (soluble, insoluble, etc.) is too small to be considered more than preliminary. Only two studies published since 1987 consider fiber type, while seven consider total fiber by source (fruit, vegetable, or grain), and five consider total dietary fiber as a single entity. The authors of a recent study state in their conclusion, "The efficacy of grain fiber in reducing the risk of colon and rectal cancer remains in question. While our results indicate some protective effect for the colon for grain fiber, most other studies do not find a grain effect" (Ref. 9). For example, the 1988 study by Slattery et al. (Ref. 40) found no effect of grain fiber.

11. Another comment provided data from an animal study that showed that wheat bran is superior to cellulose in reducing the incidence of colonic tumors in rats treated with the colonic carcinogen 1,2 dimethylhydrazine (Ref. 67). The data show that, even among insoluble fibers, differences exist in their effects on tumorigenesis. The study also showed that cellulose was more effective in reducing fecal bile acid concentrations compared to wheat bran, although this difference was apparently not statistically significant. Elevated fecal bile acid concentrations are putative risk factors for colon cancer, although in this study the cellulose group, with its lower fecal bile acid concentration, actually had significantly more colon tumors than the wheat bran group. This may further call into question the importance of dilution of fecal bile acids by fiber, a potential mechanism of action cited in this and other comments.

FDA notes that such results support its tentative conclusion in the proposed rule that fibers (even insoluble fibers) have different effects. The importance of bile acid dilution as a mechanism for effects of fiber remains to be determined.

12. One comment provided that the 1989 study by West et al. (Ref. 48), reviewed in the proposal, did control for micronutrient intake.

FDA agrees that this was incorrectly reported in the proposed rule.

13. A comment stated that the 1989 intervention study by DeCosse et al (Ref.

7) is relevant to the fiber-cancer relationship.

FDA disagrees with this comment. The patients in this study had no colons and, therefore, metabolized fiber differently and developed lesions at a different site from colon cancer patients. For these reasons, FDA believes that this study does not contribute to understanding the fiber-cancer relationship.

14. A comment cited the study of Rosen et al. (Ref. 37) to support the role of grains in reducing the risk of colon cancer.

FDA disagrees with this comment. The comment did not mention that the referenced study examined mortality data from 1969 to 1978 and surveyed food expenditures for 1978 only. Thus, the individuals who died of colon cancer had been dead for up to 10 years when the food expenditure data was collected. It is a weakness of this study that only a single year's food survey (1978) data were used, while mortality figures from the previous 10 years are incorporated. It is possible that this type of food data collection would accurately reflect the diet of the group which died from colon cancer up to 10 years earlier.

15. Several comments stated that studies with statistically insignificant but generally favorable results should be regarded as supportive of the relationship between fiber and cancer risk reduction.

FDA disagrees with this comment. Lack of statistical significance indicates that such findings could have arisen by chance and thus cannot be used to support a causal relationship.

16. One comment stated that overestimation of fiber intake (by inaccurate dietary or analytical methods) will result in underestimation of risk reduction.

FDA disagrees with this comment. Fiber consumption may be overestimated by a consistent factor in both the control and cancer groups. Such overestimation would have the effect of multiplying the intake of both groups by a common factor; for example, it could increase the intake in both groups by 30 percent. The differences between groups would also be multiplied by this common factor, and should be no less readily apparent than without this factor of overestimation, provided fiber intake is overestimated in each group to the same extent. Only if fiber intake were consistently overestimated in the cancer group, but not in the control group, would there be an apparent reduction of a protective effect. Because the same survey and analytical methods were applied to both groups, this seems an unlikely occurrence.

FDA recognizes that imprecise measures of fiber intake will usually tend to reduce associations between fiber intake and risk. Imprecise measurements do not necessarily result in overestimation of fiber, but merely inaccuracy in reporting the fiber content of certain foods. Lack of accuracy will hinder demonstration of a true relationship if one indeed exists between fiber and colon cancer risk reduction.

17. One comment noted that lack of a known mechanism of action for the putative effects of fiber in colon cancer risk reduction should not prevent the acceptance of claims of fiber's usefulness for this purpose. The comment made an analogy to drugs, arguing that they are often approved simply on evidence of efficacy, without clear knowledge of their mechanism of action.

FDA does not believe that the comparison to drug approval is apt. Drugs are substances of known chemical composition. In contrast, it is not known what fiber component or components may be responsible for the effects observed in some epidemiological studies. Fiber is a complex mixture of cellulose, hemicellulose, pectic substances, or other polysaccharides. Some of these materials, when isolated, have been found to promote rather than inhibit chemical carcinogenesis in rodents. Certainly it has not been established which of the components (all of which are types of "fiber") may reduce the risk of colon cancer in humans. Thus, more is at issue here than the mechanism of action; the identity of the actual active agent, if any, is also obscure.

18. One comment noted that fat and fiber intake correlate inversely with one another in many studies, and that this correlation is often statistically significant.

FDA notes that correlations between two dietary variables within a study do not demonstrate that either is causally related to the study endpoint (cancer). Rather, the two measures are merely associated with one another, in such a way that when one increases, the other decreases, and vice versa. Therefore, such a finding does not imply that increased fiber intake is causally related to decreased cancer incidence.

19. A comment noted that increasing fiber intake may promote decreased energy intake and that adding fiber in purified form to foods is not known to be harmful. The comment cited a 13-week study of oat hull feeding in rats as support.

FDA disagrees with this comment and notes that decreased energy intake in response to high fiber intake has not been shown consistently in all animal studies in which fiber-fed groups generally had similar body weights compared to no-fiber groups. FDA also disagrees with the broad statement that adding purified fiber to foods is not known to be harmful. A 13-week study dealing with one specific type of fiber is not sufficiently long to address chronic safety issues about all types of fiber. Nor were the full battery of toxicological endpoints customarily examined in safety evaluations performed in this study.

C. Food Claims Versus Nutrient Claims

In its proposed rule, FDA specifically requested comments on how best to inform consumers of the general dietary guidance to increase consumption of fruits, vegetables, and whole grain products that are rich sources of dietary fiber and other nutrients. In response to this request, FDA received a wide range of comments expressing strong support for health claims for foods rather than only for specific nutrients. National cancer research and health organizations, consumers, and consumer advocacy groups recommended allowing claims for whole foods. Several comments from the food industry also supported health claims for whole foods. These comments are summarized below.

20. Many comments supporting health claims for foods recommended that only those foods high in fiber should be permitted to carry a claim and that claims should not be allowed if they give the impression that dietary fiber, as a single nutrient, is responsible for the reduction in cancer risk associated with diets high in fruits, vegetables, and grain products.

FDA agrees with this comment that a health claim should not give the impression that a single nutrient is responsible for the reduction in cancer risk. Where the evidence is strongest, it is not possible to separate the effects of fiber from those of other components of the diet, such as fat, total calories, and vitamins.

21. Another comment stated that because the public is advised to increase its daily intake of dietary fiber, FDA should "exert control where it is needed" to avoid abusive use of fiber in foods and supplements. The comment stated that specific foods (e.g., no-fiber foods to which fiber is added) and fiber supplements should not be allowed to bear health claims.

FDA has determined that a health claim relating dietary fiber to cancer is

not supported by the totality of the publicly available scientific evidence. The claim that the agency is authorizing deals instead with diets high in fruits, vegetables, and grain products and may be carried by fruits, vegetables, and grain products that, without fortification, qualify as "good sources" of dietary fiber. This claim respects the state of the scientific evidence; it does not represent a position that other foods, including supplements, may not be able to bear a fiber/cancer claim in the future, should appropriate evidence demonstrating the validity of such a claim be brought to the agency's attention.

22. Other comments supported narrowly worded statements concerning overall diets and their effect on risk of cancer.

FDA agrees with this comment that a health claim, as outlined in the final rule, "Labeling; General Requirements for Health Claims for Food," should be stated in context of the total diet. Certain statements about overall diets and their effects on disease or health-related conditions would be considered dietary guidance and not regulated as health claims. In this rule, FDA is authorizing a reference to certain substances (fat and fiber) as part of a statement relating diets high in fruits, vegetables, and grain products to cancer risk.

23. Some comments stated that, if claims are allowed for fiber-containing foods, the fat content should be disclosed on the label.

FDA shares the comments' concern about the fat content of foods bearing the authorized claim. For a food to qualify for a health claim under § 101.76, it must meet the requirements for a "low fat" food as defined under § 101.62.

24. Some comments provided recommendations for developing regulatory criteria. For example, several comments stated that all foods, whether fresh or processed, should meet the same standards. Other comments stated that fiber-only products should be carefully evaluated to ensure that they qualify as foods according to criteria defined in the proposed regulations.

FDA notes new § 101.76(c)(2)(ii) contains the criteria that food must meet to qualify for the authorized health claim. A food must be or contain a fruit, vegetable, or grain product; must be "low fat;" and must be a "good source" of fiber.

25. Several comments noted that FDA acknowledges that virtually all dietary guidelines for Americans have encouraged consumption of fiber-rich foods, including whole grain cereals, fruits, and vegetables, and that comprehensive government reviews and other reviews by recognized scientific bodies have concluded that dietary patterns that include fiber-rich foods are associated with reduced risk of colorectal cancer, coronary heart disease, and other chronic diseases. The comment asserted that FDA should authorize the use of health claims for the relationship between dietary fiber and cancer.

FDA disagrees that the evidence is sufficient to support a claim that dietary fiber, as a single nutrient, is responsible for the reduction in cancer risk. However, FDA is authorizing a claim relating diets high in fiber-containing grain products, fruits, and vegetables to reduced cancer risk.

26. The American Cancer Society commented that it is unclear what aspect of fiber-rich foods reduces the risk of colorectal cancer. According to the American Cancer Society, the evidence does show, however, that fiber-rich diets reduce the risk of cancer. In its nutrition guidelines, the Society recommends that people "eat more high fiber foods, such as whole grain cereals, legumes, vegetables, and fruits." This recommendation emphasizes the importance of the total diet rather than individual components of it. The American Cancer Society recommended the use of a general food claim at the point of purchase that does not mention fiber or specific cancer sites. The comment stated further that, although the American Cancer Society does refer to the cancer prevention possibilities of fiber-rich foods in its educational materials, the American Cancer Society does not think this reference should be stated on food labels, because it is still unclear which qualities of such foods actually reduce cancer risk. For example, many fiber-rich foods are also low in fat and high in antioxidant vitamins. The American Cancer Society believes that if a claim is allowed, it should not be used on food labels unless the food meets the requirements for a "high fiber" nutrient content claim.

The National Cancer Institute supports the use of health claims on whole foods and diets high in fiber-containing foods and low in fat. Their comment stated that there is substantial and sufficient evidence that consumption of diets high in fruits, vegetables, and cereal grains are associated with the reduced risk of some types of cancer, particularly colorectal cancer. The National Cancer Institute recommended that the statement "high fiber diets" or some similar term be included in the label claim. In contrast to the American Cancer Society, the National Cancer Institute also recommended that only foods that contain naturally occurring fiber be allowed to carry a claim relating consumption of vegetables, fruits, and grain products to reduced risk of cancer. The comment stated that there is no agreement among scientific experts that fiber from fortified foods and supplements has a similar protective effect. In addition, the National Cancer Institute expressed safety concerns relative to the consumption of large amounts of fiber from a single dietary source.

FDA agrees that dietary patterns with higher intakes of vegetables (including legumes), fruits, and whole grains are associated with a reduced risk of some types of cancer (see Refs. 15, and 21 through 23 in the proposed rule (56 FR 60566) and Ref. 56 in this document). Although the specific roles of the numerous potentially protective substances in plant foods are not yet understood, populations with diets rich in these foods experience many health advantages, including lower rates of some cancers. Currently, there is not scientific agreement about whether the observed protective effects against cancer are due to a combination of the nutrient components of the foods, including fiber, to other components of the diet (for example, minerals, vitamins, etc.), or to displacement of other foods in fiber-rich diets (for example, replacement of meats, fats). Rather, the evidence currently demonstrates that it is the dietary pattern, and not a single nutrient, that is important in the reduction in risk of diseases such as cancer. If the scientific evidence were sufficient to support a health claim regarding the relationship between dietary fiber and cancer, no distinction would be made between "naturally occurring" fiber and fiber supplements. The final rule on general requirements for health claims, published elsewhere in this issue of the **Federal Register**, treats dietary supplements and conventional foods consistently.

III. Review of the Recent Scientific Evidence

A. Human Studies

FDA has reviewed studies that became publicly available after the publication of its proposed rule and data submitted as comments. These studies are summarized in Table 1.

A case control study by Soltero et al. (Ref. 56) in Puerto Rico focused on prior cholecystectomy as a risk factor for right-sided colon cancer. A food frequency questionnaire was also

administered to the subjects (or next of kin, if subjects were deceased). Cholecystectomy was confirmed to be a significant risk factor for right-sided colon cancer. Subjects with cancer reported consumption of significantly more meat and poultry and less fiber (as crude fiber) and vegetables than controls. Differences in fat intake were not statistically significant. It was not clear from the report if fiber included all sources of fiber or only cereal fiber. A protective effect was also seen for vegetables; it cannot be determined whether the effect reported for fiber was due to fiber itself or to other nutrient constituents of fiber-containing foods.

Giovannucci et al. (Ref. 62) studied a cohort of 49,296 U.S. health professionals, 40 to 75 years of age, for 2 years. The authors recorded diet by questionnaire and assessed colonic adenoma incidence based on sigmoidoscopy biopsy reports. Intake of animal fat was found to be positively associated with polyp incidence. Fiber from either fruits, vegetables, or grains were all significantly protective, whether measured as crude fiber or dietary fiber. Vegetable-associated nutrients (potassium, β-carotene, vitamins C and E) were also protective, but in a combined statistical analysis they did not account for the independent effect of fiber. Three factors limit the applicability of these findings. (1) The total fat intake of most of the subjects was low by general population standards; (2) right-sided lesions in the colon were not considered, and therefore no conclusions can be drawn about right-sided colon cancer from these data; and (3) all of the study subjects were men. A large cohort study involving U.S. nurses, the majority of whom were female, published in 1990, showed no protective effect of fiber or its components on colon cancer (Ref. 49). Giovannucci et al. do not address the differences between these two studies.

Kune et al. (Ref. 63) studied dietary factors in a case-control study of colonic polyp patients. Forty-nine patients with histologically confirmed colonic polyps (greater than 1 centimeter in size) were interviewed about their dietary practices from the previous 20 years. Interview results were compared with those of 727 community controls. Consumption of fiber and vegetables was associated with a significantly reduced relative risk (in both sexes) of polyps, while consumption of milk, beef, and beer were all associated with significantly increased risk (in males only). The study combines fiber and vegetable consumption, making it difficult to assess any independent role of fiber. Micronutrient intake from vegetables (except vitamin C), exercise, and total energy intake are potential confounding variables that were not controlled.

Gregoire et al. (Ref. 64) examined rectal cell proliferation, fecal bile acid concentration, and fecal pH in a 5-day feeding study in normal, healthy volunteers. Groups of 10 or 11 subjects consumed either a low fat/low fiber, low fat/high fiber, high fat/low fiber, or high fat/high fiber diet. Fiber was derived from a bread containing 43 percent wheat bran, 45 percent wheat flour, and 2 percent gum tragacanth as fiber sources. Approximately 41 grams (g) per (/) day of fiber were consumed in the high-fiber groups, versus 6 to 7 g/day in low fiber groups. Statistical analysis for main effects of fiber on labeling index, fecal pH, and fecal bile acid concentration revealed no statistically significant effects.

Entry of fiber into the colon influences short-chain fatty acid production. Cell culture studies have suggested that altered concentrations of short-chain fatty acids within the colon may influence colonic carcinogenesis. Butyrate production may be especially protective. Clausen et al. (Ref. 65) studied fecal short-chain fatty acid composition in 16 controls, 17 patients with resected adenomatous polyps, and 17 patients with resected colonic cancer. An analysis of fresh feces from the three groups revealed no significant differences in types or relative amounts of fecal short-chain fatty acids. Feces were also incubated in vitro for 6 to 24 hours with added boluses of wheat bran or psyllium. Under these conditions, relatively less butyrate was produced by inocula from adenoma and carcinoma patients. The authors propose that reduced butyrate production in patients may be of significance in the etiology of the neoplasms, although the butyrate content of the feces from cases was similar to that of control subjects when not incubated in vitro. It cannot be determined whether the same effects in the in vitro incubations would occur in vivo if the subjects were fed wheat bran or psyllium. The role of butyrate and other short-chain fatty acids in human colon carcinogenesis has not been clearly established.

McGarrity et al. (Ref. 66) studied the effects of fat and cellulose fiber on the growth and biochemical characteristics of two human colon cancer cell lines implanted subcutaneously in nude mice. Mice received either a low fat/low fiber diet, a high fat/low fiber diet, or a high fat/high fiber diet. The added cellulose tended to eliminate the growth-enhancing properties of a high fat diet, but the effects were not statistically significant. Differences in weight gain among the different groups at least partially explained the differences in tumor growth observed. Results with implanted tumors at a noncolonic site cannot be directly generalized to spontaneous colon tumors, which are exposed to the colonic contents as well as to the systemic blood supply.

Reduced fecal bile acid content is thought to be a beneficial factor for colon cancer risk. One comment described preliminary results of a human dietary intervention study (Ref. 58) in this area that has not yet been published. In this study, female subjects consumed wheat, corn, or oat bran supplements in addition to their usual diets. Fecal bile acids, neutral sterols, and fecal enzymatic activities of enzymes that produce fecal mutagens or carcinogens were measured before and after the intervention. Wheat bran supplementation reduced the activity of all four "risk factor" enzymes studied, while oat bran produced significant reductions in three of four enzymes, and corn bran produced significant reductions in only two of four. Alterations in stool weight are probably responsible for some of these changes. Wheat bran supplementation significantly reduced total and secondary bile acid concentration in feces, while oat bran and corn bran did not.

B. Conclusions From New Studies

These additional studies provide further data on the possible link between consumption of dietary fiber consumption and reduced risk of colon cancer. With the exception of the study by Giovannucci et al. (Ref. 62), none of the studies provides evidence of an independent contribution of fiber itself (distinct from its presence in food) to risk reduction. Rather, the studies show a relationship between diets rich in fiber-containing foods and reduced risk of cancer. The Giovannucci et al. study is limited in its applicability, however, as only lesions of the descending colon were considered, and the subjects were men who already consumed a diet lower in fat and higher in vegetables than a typical U.S. diet.

The preliminary results of Reddy's study (Ref. 58) on the effects of amount and type of dietary fiber on colonic bacterial enzymes and bile acids in humans support FDA's observations that insoluble fiber has not consistently been shown to be the protective fiber fraction. Wheat bran and corn bran (both largely insoluble fibers) exerted opposite effects in this risk factor study, as they do in most published animal

carcinogenesis studies. It must also be noted that the risk factors measured in this study have only postulated significance in the etiology of human colon cancer at the present time.

Although the current scientific evidence does not support a specific health claim for dietary fiber and reduced risk of cancer, the data do support a relationship between diets high in fiber-rich foods and low in fat and a reduced risk of some forms of cancer. Therefore, as discussed below, FDA will allow a health claim on vegetables, fruits, and grain products relating diets high in these foods to a reduced risk of cancer, and specifying that these foods contain dietary fiber.

IV. Decision to Deny a Health Claim Relating Dietary Fiber to a Reduced Risk of Cancer

Overall, the currently available scientific evidence is not sufficiently conclusive or specific for fiber per se to justify use of a health claim relating the intake of dietary fiber to a reduced risk of cancer. A major limitation in designing and evaluating research studies has been the need for better defined measures of dietary fiber and standardized descriptions for source, type, and amount of dietary fiber. Commonly used analytical methodologies do not detect many of the characteristics that may vary among fibers and that may be related to biological function (e.g., particle size, chemical composition, water-holding capacity). The inability to detect many of the differences among fibers and the general lack of clear evidence as to the mechanisms of action of fibers raise questions about the ability of commonly used analytical measures of dietary fiber to adequately predict biological actions of specific fibers. Therefore, for these reasons, new § 101.71(a) is added to reflect FDA's decision not to authorize use of a health claim relating dietary fiber to a decreased risk of cancer.

FDA's decision is consistent with recent recommendations in the Institute of Medicine's report "Nutrition Labeling: Issues and Directions for the 1990s" (Ref. 57). This report notes that there has been great interest in the specific effects of dietary fiber on several chronic diseases. According to the report, the strongest argument for an increased consumption of dietary fiber is the important contribution it makes to normal bowel function. Clear scientific associations of fiber intake with the incidence of cancer have not been made. The report indicates that one reason for this may be the difficulty in designing appropriate experiments to test specifically for the effect of dietary fiber. Foods high in dietary fiber are also generally low in calories and total and saturated fatty acids and devoid of cholesterol; thus, determination of a specific fiber effect in a feeding study is difficult. Moreover, according to the report, foods have a variety of fiber components and each may have different actions. Chemically and physiologically, cellulose, lignin, hemicellulose, pectin and alginate (all relatively purified fiber types) behave differently. Wheat bran, oat bran, and rice bran (all heterogenous mixtures of fibers) are not similar in composition. It is also very difficult to analyze dietary fiber chemically, and thus it is hard to correlate the role of specific fiber components to health effects (Refs. 30 and 57).

Therefore, FDA is not authorizing the use on the labels and labeling of foods of health claims relating to an association between the ingestion of dietary fiber and a reduction in the risk of cancer. In reaching this decision, the agency considered all comments received in response to its proposed rule (56 FR 60566), and reviewed the scientific literature that became publicly available after the proposal's publication and data submitted with comments.

V. Decision to Allow a Health Claim on Foods Relating Diets Low in Fat and High in Fiber-Containing Grain Products, Fruits, and Vegetables to a Reduced Risk of Cancer

FDA has reviewed numerous authoritative documents, including Federal Government reports, as well as recent research on dietary fiber and cancer risk. In addition, the agency considered all comments received in response to its proposed rule. The agency has concluded that the publicly available scientific evidence supports an association between diets low in fat and high in fiber-containing grain products, fruits, and vegetables and reduced risk of cancer.

FDA agrees with the comments that argue that dietary patterns that are low in fat and high in fiber-containing grain products, fruits, and vegetables (including legumes), are associated with a decreased risk of some types of cancer. Although the specific role of total dietary fiber, fiber components, and the multiple nutrients and other substances contained in these foods are not yet fully understood, many studies have shown that diets high in fiber-containing foods are associated with reduced risk of some types of cancer.

Thus, the conclusion that diets low in fat and high in fiber-containing grain products, fruits, and vegetables, foods also generally low in fat, are associated with a reduced risk of cancer is consistent with the available scientific evidence. As discussed in the final rule on general requirements for health claims, published elsewhere in this issue of the **Federal Register**, statements about good nutrition that do not expressly or by implication refer to a substance are considered dietary guidance and not health claims. In this rule, FDA is authorizing the inclusion of a reference to dietary fiber in a statement about the value of grain products, fruits, and vegetables in reducing cancer risk. Thus, the health claim permitted under this regulation to be used on the label or labeling of certain foods associates diets low in fat and high in fiber-containing grain products, vegetables, and fruits with a reduced risk of some cancers.

VI. Description of and Rationale for Components of the Health Claim.

A. Relationship and Significance Statements

In new § 101.76(a), the summary of the relationship between diets high in fiber-containing grain products, fruits, and vegetables and reduced cancer risk is consistent with the conclusions reached in the review of the scientific evidence. It is not known whether it is fiber, per se, or some other substance in fruits, vegetables, and grain products that functions as the protective agent; or, if it is fiber, what types and characteristics of the heterogeneous family of fiber compounds are most beneficial. Yet, because of the usefulness of dietary fiber in identifying the types of foods most likely to correlate with reduced cancer risk, fiber is specifically identified as being characteristic of the protective dietary pattern. Thus fiber can serve as the identifying marker. Other components of the relationship statement, for example, risk factors, have been indicated, as in other authorized health claims.

New § 101.76(b), on the significance of the relationship between consumption of diets low in fat and high in fiber-containing grain products, fruits, and vegetables and reduced risk of cancer, includes the information that U.S. diets tend to be high in fat and low in grains, fruits, and vegetables. A discussion of current dietary guidelines on recommended servings of grain products, fruits, and vegetables is also provided.

B. Nature of the Claim

In new § 101.76(c)(2)(i), FDA is authorizing a health claim relating

substances in diets low in fat and high in fiber-containing grain products, fruits, and vegetables to reduced risk of cancer. In new § 101.76(c)(2)(i)(A), the agency is requiring, consistent with other authorized claims, that the relationship be qualified with the terms "may" or "might." These terms are used to indicate that not all persons can necessarily expect to benefit from these dietary changes.

In new § 101.76(c)(2)(i)(B), the agency, consistent with other authorized claims, is requiring that the claim not indicate that all cancers may be affected, but rather that the risk of "some types of cancer" or "some cancers" may be reduced. The relationship between dietary factors and various types of cancers is variable; in many cases, the available data are inadequate to specifically identify which cancers may be affected.

In new § 101.76(c)(2)(i)(C), the agency is requiring that the claim be limited to grain products, fruits, and vegetables that contain dietary fiber. As noted in the conclusions reached from the available scientific evidence, it is not known what fiber substance or other substances in grain products, fruits, and vegetables are responsible for their protective effect. A role for dietary fiber has been hypothesized and has biological plausibility. Intakes of fiber and other nutrients from grains, fruits, and vegetables are correlated with reduced cancer risk. By requiring that the characterizing nutrient be identified as characteristic of a dietary pattern rich in fiber-containing grains, fruits, and vegetables, without specifically attributing the cause to a nutrient, the claim is more consistent with the current scientific knowledge. The claim should also minimize consumer confusion, because its wording is similar to current dietary guidelines from the U.S. Government, including the National Cancer Institute.

New § 101.76(c)(2)(i)(D) requires that health claims indicate that development of cancer depends on many factors. This requirement is intended to prevent consumers from being misled that grain product, fruit, and vegetable intake is the only factor connected with cancer risk. In new § 101.76(c)(2)(i)(E), FDA, consistent with other authorized health claims, is prohibiting the attribution of a specific reduction in risk of cancer to diets low in fat and high in fiber-containing grain products, fruits, and vegetables. In new § 101.76(c)(2)(i)(F) and (c)(2)(i)(G), FDA is prohibiting, consistent with other authorized health claims, more specific use of dietary terms than is warranted by the current state of the scientific evidence. These requirements also standardize use of these terms, thus minimizing consumer confusion as they compare food labels across products, or as they compare a health claim to the nutrition information panel.

C. Nature of the Food

New § 101.76(c)(2)(ii)(A) requires that the food bearing the health claim be or contain a grain product, fruit, or vegetable. Because the claim relates to diets high in these foods, it would not make sense for it to appear on the labeling of another type of food. A health claim that appears on a food that meets all the requirements in § 101.76(c)(2)(ii), but contains only a trivial amount of grain product, fruit, or vegetable, could be considered misleading and might misbrand the food under section 403(a) of the act. FDA, consistent with the requirements for the health claim on dietary fat and cancer (published elsewhere in this issue of the **Federal Register**), is requiring in new § 101.76(c)(2)(ii)(B) that foods bearing the health claim be "low fat" foods, or alternatively, belong to a class of products that is "low in fat." Low fat diets are associated with reduced cancer risks. Low or negligible fat is also one of the characterizing features of diets rich in grain products, fruits, and vegetables. Because the effect of fat is not readily separated from the effect of other nutritive components of grain products, fruits, and vegetables, it is being made a qualifying nutrient.

In new § 101.76(c)(2)(ii)(C), FDA is requiring that grains, fruits, and vegetables, bearing the authorized health claim qualify as a "good source" (greater than or equal to 10 percent of the daily reference value (DRV)) for dietary fiber. The requirement that these foods contain 10 percent of the DRV for dietary fiber is being set as a specific alternate to the 20 percent (i.e., "high") requirement for qualifying nutrients in the final rule on general requirements for health claims, published elsewhere in this **Federal Register**. This alternate level was deemed useful to assure that most grain products, fruits, and vegetables, would be eligible for this health claim, because these foods in general have been correlated with reduced cancer risk, and because they are significant sources of dietary fiber in the U.S. dietary pattern. Without this alternate level, very few grain products, fruits, and vegetables, would qualify for the health claim, which would be contrary to the available scientific evidence and to the purpose of health claims.

This section also requires that foods qualify as a good source of fiber based on their natural level of fiber. This means that foods which require fortification with dietary fiber, in order to meet the qualifying criteria for the health claim, cannot bear the claim. This requirement is consistent with the scientific basis for the claim, that is, that grains, fruits, and vegetables, in their native form correlate with reduced cancer risk. Because there are not sufficient data that specifically identify dietary fiber, or particular components of fiber, as causal and because this nutrient is being used as a marker for the substance or substances in grain products, fruits, and vegetables, that provide the observed protective effect, it is the native composition of the foods that identifies their usefulness. At the same time, this requirement does not prohibit fortification of qualifying foods with dietary fiber, once the qualifying level has been met naturally.

D. Optional Information

Under new § 101.76(d), similarly to other authorized health claims, health claims may identify additional risk factors for cancer. The regulation specifies the factors that may be listed; all are risk factors about which there is general scientific agreement. This additional information can provide a context that is useful for an understanding of the relationship of the diet to the disease, but manufacturers are cautioned that it should not be presented in a way that is misleading to the consumer. A health claim may also indicate that reductions in fat intake and consumption of fruits, vegetables, and grain products are part of a total dietary pattern that is consistent with the latest "Nutrition and Your Health: Dietary Guidelines for Americans," published jointly by the U.S. Department of Agriculture and the U.S. Department of Health and Human Services (Ref. 45). Consistent with other health claim regulations, the claim may also include information on the prevalence of cancer in the United States. In order to ensure that this information is valid, the agency is requiring that it come from one of three specified authoritative sources.

E. Model Health Claims

In new § 101.76(e) FDA is providing several model health claims to illustrate the requirements of new § 101.76. FDA is not prescribing specific language for claims, but certain elements are required, and these models include the required elements.

VII. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a

type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VIII. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), and along with the food labeling proposals, the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act, and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.71 is amended by adding new paragraph (a) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(a) Dietary fiber and cancer.

3. New § 101.76 is added to subpart E to read as follows:

§ 101.76 Health claims: fiber-containing grain products, fruits, and vegetables and cancer.

(a) *Relationship between diets low in fat and high in fiber-containing grain products, fruits, and vegetables and cancer risk.* (1) Cancer is a constellation of more than 100 different diseases, each characterized by the uncontrolled growth and spread of abnormal cells. Cancer has many causes and stages in its development. Both genetic and environmental risk factors may affect the risk of cancer. Risk factors include: A family history of a specific type of cancer, cigarette smoking, overweight and obesity, alcohol consumption, ultraviolet or ionizing radiation, exposure to cancer-causing chemicals, and dietary factors.

(2) The scientific evidence establishes that diets low in fat and high in fiber-containing grain products, fruits, and vegetables are associated with a reduced risk of some types of cancer. Although the specific role of total dietary fiber, fiber components, and the multiple nutrients and other substances contained in these foods are not yet fully understood, many studies have shown that diets low in fat and high in fiber-containing foods are associated with reduced risk of some types of cancer.

(b) *Significance of the relationship between consumption of diets low in fat and high in fiber-containing grain products, fruits, and vegetables and risk of cancer.* (1) Cancer is ranked as a leading cause of death in the United States. The overall economic costs of cancer, including direct health care costs and losses due to morbidity and mortality, are very high.

(2) U.S. diets tend to be high in fat and low in grain products, fruits, and vegetables. Studies in various parts of the world indicate that populations who habitually consume a diet high in plant foods have lower risks of some cancers. These diets generally are low in fat and rich in many nutrients, including, but not limited to, dietary fiber. Current dietary guidelines from Federal government agencies and nationally recognized health professional organizations recommend decreased consumption of fats (less than 30 percent of calories), maintenance of desirable body weight, and increased consumption of fruits and vegetables (five or more servings daily), and grain products (six or more servings daily).

(c) *Requirements.* (1) All requirements set forth in § 101.14 shall be met.

(2) Specific requirements. (i) *Nature of the claim.* A health claim associating diets low in fat and high in fiber-containing grain products, fruits, and vegetables with reduced risk of cancer may be made on the label or labeling of a food described in paragraph (c)(2)(ii) of this section, provided that:

(A) The claim states that diets low in fat and high in fiber-containing grain products, fruits, and vegetables "may" or "might" reduce the risk of some cancers;

(B) In specifying the disease, the claim uses the following terms: "some types of cancer," or "some cancers";

(C) The claim is limited to grain products, fruits, and vegetables that contain dietary fiber;

(D) The claim indicates that development of cancer depends on many factors;

(E) The claim does not attribute any degree of cancer risk reduction to diets low in fat and high in fiber-containing grain products, fruits, and vegetables;

(F) In specifying the dietary fiber component of the labeled food, the claim uses the term "fiber", "dietary fiber" or "total dietary fiber"; and

(G) The claim does not specify types of dietary fiber that may be related to risk of cancer.

(ii) *Nature of the food.* (A) The food shall be or shall contain a grain product, fruit, or vegetable.

(B) The food shall meet the nutrient content requirements of § 101.62 for a "low fat" food.

(C) The food shall meet, without fortification, the nutrient content requirements of § 101.54 for a "good source" of dietary fiber.

(d) *Optional information.* (1) The claim may include information from paragraphs (a) and (b) of this section, which summarize the relationship between diets low in fat and high in fiber-containing grain products, fruits, and vegetables, and some types of cancer and the significance of the relationship.

(2) The claim may identify one or more of the following risk factors for development of cancer: Family history of a specific type of cancer, cigarette smoking, overweight and obesity, alcohol consumption, ultraviolet or ionizing radiation, exposure to cancer causing chemicals, and dietary factors.

(3) The claim may indicate that it is consistent with "Nutrition and Your Health: Dietary Guidelines for Americans," U.S. Department of Agriculture (USDA) and Department of Health and Human Services (DHHS), Government Printing Office.

(4) The claim may include information on the number of people in the United States who have cancer. The sources of this information must be identified, and it must be current information from the National Center for Health Statistics, the National Institutes of Health; or "Nutrition and Your Health: Dietary Guidelines for Americans," USDA and DHHS, Government Printing Office.

(e) *Model health claims.* The following model health claims may be used in food labeling to characterize the relationship between diets low in fat and high in fiber-containing grain products, fruits, and vegetables and cancer risk:

(1) Low fat diets rich in fiber-containing grain products, fruits, and vegetables may reduce the risk of some types of cancer, a disease associated with many factors.

(2) Development of cancer depends on many factors. Eating a diet low in fat and high in grain products, fruits, and vegetables that contain dietary fiber may reduce your risk of some cancers.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

21 CFR Part 101

[Docket No. 91N–0099]

RIN 0905–AB67

Food Labeling: Health Claims and Label Statements; Dietary Fiber and Cardiovascular Disease

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision not to authorize the use on the label or labeling of foods of health claims relating to an association between dietary fiber and cardiovascular disease (CVD). However, FDA is authorizing a health claim relating diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain dietary fiber (particularly soluble fiber), to a reduced risk of coronary heart disease (CHD). This action is in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims, and was developed in accordance with the final rule on general requirements for health claims, published elsewhere in this issue of the Federal Register.

On the basis of the totality of the publicly available scientific evidence, including recently available evidence, the agency has concluded that there is significant scientific agreement among qualified experts that a claim relating diets low in saturated fat and cholesterol, and high in fruits, vegetables, and grain products that contain soluble fiber, to reduced risk of CHD is supported. The evidence is not sufficient to attribute the reduction in risk to soluble fiber or to a specific type or characteristic of soluble fiber, or to other components of these diets.

EFFECTIVE DATE: May 8, 1993.

FOR FURTHER INFORMATION CONTACT: Joyce J. Saltsman, Center for Food Safety and Applied Nutrition (HFS–165), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–5916.

SUPPLEMENTARY INFORMATION:

I. Background

In the Federal Register of November 27, 1991 (56 FR 60582), FDA proposed to deny the use on food labeling of health claims relating diets high in dietary fiber to reduced risk of CVD. The proposed rule was issued under provisions of the 1990 amendments (Pub. L. 101–535) that bear on health claims and in accordance with the proposed general requirements for health claims for food (56 FR 60537, November 27, 1991). As amended in 1990, the Federal Food, Drug, and Cosmetic Act (the act) provides that a food is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition unless the claim is made in accordance with sections 403(r)(3) or (r)(5)(D) of the act (21 U.S.C. 343(r)(3) or (r)(5)(D)).

Section 3(b)(1)(A) of the 1990 amendments specifically requires that the agency determine whether health claims respecting 10 nutrient/disease relationships meet the requirements of section 403(r)(3) or (r)(5)(D) of the act. The relationship between dietary fiber and CVD is one of the claims required to be evaluated. In the proposed rule published in the Federal Register of November 21, 1991 (56 FR 60582), FDA limited its review of the science to those aspects of the dietary fiber/CVD relationship for which the strongest scientific evidence and agreement already existed: dietary soluble fiber and CHD.

In the proposed rule, FDA requested written comments on its tentative determination not to authorize a health claim for dietary fiber and CVD. FDA also requested comments on the following issues: (1) Should the agency permit a claim on the label or in labeling of foods that states that diets high in fruit, vegetables, and whole grains are associated with a reduced risk of certain forms of cancer and CVD?; (2) If such statements should be permitted, what criteria should be used to identify foods that are eligible for such statements?; (3) What measures should the agency adopt to assure that consumers are not misled as to the benefit of consuming a specific product?; and (4) Does FDA have the authority to allow and should it allow health claims for foods as well as nutrients?

On January 30 and 31, 1992, FDA held public hearings on all aspects of the proposed rules published in response to the 1990 amendments, including health claims for dietary fiber and CVD. In addition, because of new evidence identified from literature searches and new data submitted with comments to the proposed rule, FDA reopened the comment period on dietary fiber and CVD for 30 days (57 FR 32751, July 23, 1992).

In response to its proposed rule on dietary fiber and CVD, the agency received approximately 130 comments from consumers, consumer advocacy groups, State health departments, organizations of health professionals, the food industry, and Government agencies. A number of comments were received that were more appropriately answered in other dockets, and these were forwarded to the appropriate docket for response.

Most of the comments specific to the proposal for a health claim for fiber and CVD provided explanations in support of or in opposition to provisions of the proposed regulation. Some of the comments contained relevant scientific studies not included in the agency's proposed rule. These additional studies and those identified through literature searches that had not been previously reviewed in the proposal (56 FR 60582) are included in the agency's review below. The agency has summarized and responded to issues raised in the comments in section III. of this document.

II. Updated Review of Scientific Evidence

FDA, to ensure that it had not overlooked new and significant scientific data, reviewed human studies published since the publication of the proposed rule that it had identified in a standard literature search. In addition, FDA carefully reviewed all relevant scientific data submitted as comments. The availability of the new data was announced in a notice of reopening of comment period (57 FR 32751).

A. Human Studies

Detailed summaries of studies discussed below are presented in Table 1. FDA's explanation for separately evaluating studies on mildly to moderately hypercholesterolemic individuals and normocholesterolemic individuals is found in its proposed rule (56 FR 60587). Multiple sources of soluble fiber, including oat bran and other cereal brans, legumes, pectin, psyllium, and guar gum, were used in these studies.

1. Hypercholesterolemics: "typical" or "usual" diets

Leadbetter et al. (Ref. 83) evaluated the hypocholesterolemic effects of increasing intakes of β-glucan, the major type of dietary soluble fiber in oat bran. A four-by-four Latin square design was used in this randomized intervention study with 40 hypercholesterolemic (total serum cholesterol 250 to 348 milligram/deciliter (mg/dL)) men and women, ages 25 to 64, in New Zealand. Subjects added 0, 30, 60, and 90 grams/day (g/day) oat bran to their usual diet

for 1-month intervals. There was no wash-out between periods. Oat bran was provided in weighed packages and detailed advice and recipes were provided on how to incorporate it into the diet. The total dietary fiber content of the regular diets, without oat bran, ranged from 23 to 27 g/day. Results showed no significant effect of oat bran on serum cholesterol at any dose. There was no dose-related trend and no correlation between bran dose and changes in serum cholesterol. The authors stated that the oat bran used in this study was lower in soluble fiber (3.7 to 4.2 percent β-glucan) than oat bran used in studies showing a significant lowering of serum cholesterol with oat bran supplementation.

Cara et al. (Ref. 84) evaluated the hypocholesterolemic properties of wheat germ in 10 hypercholesterolemic men and women (serum cholesterol 254 to 367 mg/dL), ages 35 to 68 years. Subjects consumed their regular diets for 1 week, then added 30 g/day wheat germ (2.9 g dietary fiber) for 4 weeks. At the end of the treatment period, subjects were monitored for an additional 4 weeks with no supplementation. Their base diet included 13.6 g/day dietary fiber and 6 g/day alcohol. Serum cholesterol decreased significantly (8.6 percent) after wheat germ intervention and returned to baseline during the 1 month followup period. Dietary soluble fiber and total saturated fat before and during the treatment period were not reported. The authors speculate that the high vegetable protein content of wheat germ could account for the observed results.

Karlander et al. (Ref. 85) evaluated the hypocholesterolemic properties of beet fiber in 13 hypercholesterolemic noninsulin-dependent diabetics mellitus (NIDDM) men and women (mean serum cholesterol of 275 mg/dL). Five subjects were on chronic beta blockers and diuretics and eight were on diet treatment with sulfonylurea (SU). This was a controlled, randomized intervention trial with cross-over design. The study was divided into three 6-week periods with a run-in period followed by either fiber intervention (20 g/day beet fiber) or the subject's regular diet for 6 weeks, then cross-over to the other diet. Obese subjects were given dietary advice to aid in weight control. Results showed no significant difference in total serum cholesterol between control and fiber periods for subjects advised to reduce energy intake. The SU group showed significantly decreased (10 percent) serum cholesterol during the fiber phase (total cholesterol decreased from 275 to 247 mg/dL). The SU group had a slight but significant loss of body mass during the run-in period only. There was no effect on serum triglycerides.

Spiller et al. (Ref. 87) evaluated the cholesterol-lowering properties of guar gum compared to oat bran in a 3-week, intervention trial with cross-over. Thirteen men and women, mean age 62 years, with mild to moderate hypercholesterolemia (serum cholesterol 204 to 276 mg/dL), were randomized to receive either 15 g (11 g dietary fiber, of which there was 10 g soluble fiber) of guar gum per day or 77 g/day (11 g dietary fiber, 5 g soluble fiber) oat fiber source, divided into three servings. The fibers were provided in weighed packets with instructions to mix the fiber with water or juice and consume before each main meal. After 21 days, subjects switched to the other fiber source. There was no wash-out between test periods. Blood samples were collected on days 14 and 21 during treatment periods. Results showed a significant reduction in serum cholesterol, compared to baseline, for both groups. Guar reduced serum cholesterol 11 percent and oat fiber 6 percent. Maximum cholesterol reduction was experienced after 14 days on the test fiber. No significant change occurred in serum cholesterol between days 14 and 21 on either test fiber, with serum cholesterol values increasing slightly but not significantly. Factors confounding these results include small sample size, the absence of a wash-out between test periods, and short treatment periods. Dietary intakes of soluble fiber were not reported.

Kawatra et al. (Ref. 88) reported significant reductions in total serum cholesterol and low density lipoprotein (LDL)-cholesterol in 20 overweight Indonesian men and women with mild to moderate hypercholesterolemia consuming guar gum. Subjects consumed 15 g/day guar gum with their normal diet for 6 weeks. The guar was consumed 15 minutes before the main meal in the form of biscuits (10 g guar) and mixed (5 g guar gum) with a flavored drink. Total serum cholesterol decreased 16.7 percent and LDL-cholesterol decreased 26.5 percent. Intake of total dietary fiber, dietary soluble fiber, and saturated fat were not reported.

Tinker et al. (Ref. 89) evaluated the cholesterol-lowering properties of prunes in a randomized, cross-over trial. Forty-one men, ages 29 to 79, with mild to moderate hypercholesterolemia (serum cholesterol 201 to 290 mg/dL) consumed either grape juice (360 milliliter (mL)/day) or 12 prunes (100 g/day) for 4 weeks followed by cross-over to other diet for an additional 4 weeks. Prunes provided 6 to 7 g of total dietary fiber and 3.6 to 4.2 g of soluble fiber as pectin. Base diets included 18 g of total dietary fiber during the grape juice period and 24 g of fiber during the prune period. Four to five percent of the energy was from alcohol. There was no significant difference between serum cholesterol on the prune diet and on the grape juice diet.

A final report by Earll et al., July 1986 (Ref. 90), was submitted with one of the comments. This was an intervention study with seven free living hyperlipidemic (serum cholesterol ranged from 261 to 346 mg/dL) male and female patients. Subjects were asked to consume 24 g/day of corn fiber (containing less than 2 g soluble fiber) for 6 weeks, then 48 g/day corn fiber for an additional 6 weeks with their regular diet. The test period was followed by an 8-week wash-out period. Actual consumption of corn fiber was slightly less according to records kept by the subjects. Total cholesterol was reduced, on average from 298 to 253 mg/dL (significant), although much smaller changes were seen in two subjects, and one subject had an increase in serum cholesterol during the study period. In all but one of the subjects, serum cholesterol remained above 200 mg/dL with fiber intervention, suggesting dietary therapy was not adequate. The dietary intakes of the subjects before and during the test period were not recorded.

Whyte et al. (Ref. 104) reported significant reductions in serum cholesterol in 23 men with mild hypercholesterolemia (total cholesterol ranged from 209 to 259 mg/dL) consuming oat bran. Subjects consumed 123 g/day oat bran or 54 g/day wheat bran cereal with their regular diets for 4 weeks followed by cross-over to the other fiber cereal. All subjects consumed wheat cereal during a 3-week baseline period prior to randomization to test groups. Total dietary fiber and fat intake were approximately the same between groups. Total serum cholesterol and LDL-cholesterol, when consuming oat bran, decreased 4 percent and 5.5 percent, respectively, compared to wheat bran. The authors note that one of their earlier studies with 12 g of oat bran showed significant decreases in serum cholesterol of 6 percent compared to 12 g of wheat bran. According to their analyses, both oat brans were similar in composition (Ref. 104). The smaller decrease in serum cholesterol reported in this study as compared to some other oat bran studies, not conducted by these authors, may be due to the difference in β-glucan

content of different strains of oats. This 4-week study does not address long-term effectiveness of oat bran intervention.

Uusitupa et al. (Ref. 100), in a randomly-allocated, double-blind parallel group trial, tested the effects of guar gum on 39 individuals with NIDDM (mean serum cholesterol of groups: 253 and 237 mg/dL). The test group received 5 g of guar gum three times per day (estimated total of 10 g soluble fiber) before meals for 3 months, while the control group received 5 g of wheat flour 3 times per day before meals. After 3 months, the control group was switched to guar and both groups were followed for an additional 10 months. At the end of 3 months, the guar group showed a significant lowering of serum total cholesterol. Over the remaining 10 months, the group which began as the test group had an increase in total cholesterol, although it remained significantly lower than prior to the trial. The group which began as the control group, but switched to guar, demonstrated the lowest serum cholesterol during month 5 (208 mg/dL). This was followed by increasing serum cholesterol to a maximum at month 11 (242 mg/dL). After 12 months, serum cholesterol for this group was 233 mg/dL. Significant weight loss occurred in both the control and treatment groups to a similar degree. The dietary intakes for both groups were not reported.

Spencer and Gee (Ref. 109) evaluated the cholesterol-lowering properties of apple juice supplemented with 10 g of dietary fiber (70 percent soluble fiber, predominantly from gum arabic) versus plain apple juice. Thirty-one mildly hypercholesterolemic men (serum cholesterol between 200 and 270 mg/dL) consumed their regular diets in this 6-week cross-over, blinded trial. With both ordered groups totalled, there was a significant decrease in serum total cholesterol and LDL-cholesterol during the period of consumption of fiber-enriched juice. When order of presentation is considered, there were inconsistencies in the changes. The group which began the trial with the placebo did not show any change from baseline in serum cholesterol during the placebo phase, whereas the group which received the placebo during the second half of the trial maintained the lower cholesterol level which occurred during the fiber supplementation period. Cholesterol intake was significantly higher in the juice-only group.

Niemi et al. (Ref. 99), in a double-blind, cross-over trial, reported significant lowering of serum cholesterol in a group that received 15 g/day guar gum (estimated total of 10 g soluble fiber) as a supplement for 12 weeks when compared to the group which received cellulose, the placebo. The 16 women and 6 men chosen as subjects were all (NIDDM) between the ages of 40 and 76. Nineteen of these subjects were on medication for their diabetes. Although the patients were advised to maintain their normal diets, no dietary measurements were reported to verify this.

Kirsten et al. (Ref. 97) evaluated the hypocholesterolemic properties of guar gum in 13 men and women with type IIa and IIb hyperlipidemia (serum cholesterol concentration >251 mg/dL). The study was divided into three phases: the 30-day pretreatment phase (baseline), the 60-day treatment, and the 60-day post-treatment period. During the treatment phase, subjects consumed 4 g of guar gum, mixed with water or juice before breakfast, lunch, and dinner (12 g guar/day, estimated—8 g soluble fiber). Subjects were only instructed to avoid cholesterol-rich foods during the study period. Both total serum cholesterol and LDL-cholesterol decreased significantly compared to pretreatment levels. During the post-treatment period, serum cholesterol returned to baseline and LDL-cholesterol increased above baseline. The dietary intakes of the subjects during each phase of the study were not reported.

Cerda et al. (Ref. 105) evaluated the hypocholesterolemic effects of grapefruit pectin in a double-blind, placebo-controlled, cross-over study. Twenty-seven hypercholesterolemic men and women (mean serum cholesterol of 275 mg/dL) consumed 15 g of grapefruit pectin (27 tablets, 9 per meal) or 15 g of flour (also in tablet form) per day for 4 weeks followed by a 4-week wash-out before cross-over. During the pectin period total cholesterol decreased by almost 8 percent and LDL-cholesterol by 11 percent (both significantly lower compared to baseline). There was no change in serum cholesterol during the placebo period. The dietary intake of the subjects during each period of the study was not reported. The short test periods do not address long-term usefulness of pectin.

Haskell et al. (Ref. 106) evaluated the hypocholesterolemic properties of four isolated, purified soluble fibers in four separate trials. All subjects had serum cholesterol levels between 200 and 280 mg/dL and were randomized to 1 of the four studies. Study one was a 12-week intervention trial using a powdered soluble fiber mixture providing 17.2 g/day of soluble fiber. The powder consisted of acacia gum (9.7 g), psyllium (4.9 g), and guar gum (2.6 g). The soluble fiber mixture was tested against a fructose placebo (15 g/day). Results showed no statistically significant changes from baseline to 6 or 12 weeks within or between groups. Study two was a 4-week intervention testing 15 g/day of acacia gum powder against 15 g/day fructose powder. There was no significant change from baseline or compared to the placebo. Study three was an 8-week cross-over trial using 10 g/day of guar (estimated 6.7 g soluble fiber) as a control and a 15 g/day fiber mixture of pectin (3.9 g), psyllium (6.3 g), guar (3.3 g), and locust bean gum (1.5 g). Each test period was 4 weeks. Results showed both the guar and the fiber mixture reduced serum cholesterol (approximately 10 percent and 8 percent, respectively), LDL-cholesterol (approximately 14 percent and 12 percent, respectively), and high density lipoprotein (HDL)-cholesterol (about 6 percent) significantly. Study four was a 4-week dose-response study with increasing amounts of soluble fiber from a mixture of pectin, psyllium, guar, and locust bean gum. Three groups received either 5 g, 10 g, or 15 g/day of the mixture. Results showed that the serum cholesterol and LDL-cholesterol of the group consuming 15 g/day was significantly lower than the placebo.

A 1984 study by Anderson et al. (Ref. 110) was submitted with comments in support of a long-term hypocholesterolemic effect of soluble fiber from oat bran and beans. Ten men, ages 46 to 66, with serum cholesterol above 260 mg/dL were randomly assigned to oat bran or bean-supplemented diets for 21 days following a 7-day baseline period on a metabolic ward. The base diet was a "typical" American diet with 38 percent of calories as fat and 450 mg cholesterol. To this diet, the subjects added either 100 g of oat bran or 100 g of dried beans per day. Both of these diets provided 18 g of total soluble fiber and 48 to 50 g of total plant fiber per day. Before discharge, the subjects were instructed on the use of a high fiber (50 g of total fiber per day) maintenance diet with oat or bean product supplements at home. The high fiber diet was also low in fat (30 percent of calories as fat), low in saturated fat (10 percent of calories), and low in cholesterol (150 mg/day). Ten men were followed on their home diets for 24 weeks and 4 for 99 weeks. Results of the metabolic ward phase of the study showed that the oat bran and bean diets lowered serum cholesterol significantly (23 percent) over the 3-week period compared to baseline. At 24 weeks (the followup phase), serum

cholesterol levels were significantly (26 percent) lower than baseline. Cholesterol levels in the four men followed for 99 weeks were 23 percent lower than baseline (significant at $p<0.0025$). Reductions in LDL-cholesterol were also significant during both phases of the study. HDL-cholesterol decreased significantly (20 percent) during the metabolic ward phase but increased during the long-term followup. All 10 subjects lost approximately 4 pounds (lb) (significant at $p<0.0025$) during the metabolic ward phase of the study. The investigators reported that changes in body weight were not significantly correlated with the changes in serum cholesterol. An additional 4 lb of weight was lost during the 24-week phase of followup.

An unpublished study (Ref. 119) evaluated the cholesterol lowering properties of oat gum in hypercholesterolemics (mean serum cholesterol of 255 mg/dL). Instant oat gum (3.6 g) or a placebo (maltodextrin) were mixed with a noncarbonated diet fruit drink (250 mL) and consumed twice a day at each main meal for 4 weeks. There was a 3-week wash-out between treatment periods and after the last oat gum period. Subjects were randomly assigned to start the treatment period with either the oat gum beverage or the placebo. Results showed significantly lower serum cholesterol after 4 weeks on oat gum compared to both the baseline ($p = 0.02$) and the placebo ($p = 0.001$). Although subjects were asked to maintain their weight, subjects' weights were not reported.

Bridges et al. (Ref. 120) evaluated the effect of oat bran on serum cholesterol and serum acetate in hypercholesterolemic men admitted to a metabolic ward. Animal studies have shown that both acetate and propionate inhibit cholesterol synthesis (Ref. 120). The 20 subjects were divided into two groups: Wheat bran group (mean serum cholesterol of 252 mg/dL) and oat bran group (mean serum cholesterol of 305 mg/dL). Following 1 week on a typical American diet, the diets were supplemented for 21 days with either 110 g of oat bran per day or 40 g of wheat bran. Results showed that the oat bran group experienced significantly lower ($p = 0.05$) serum cholesterol than the wheat bran group. However, in the wheat bran group, the baseline cholesterol level had been higher than in the oat bran group. There was a significant ($p = 0.001$) weight loss in both groups. The weight loss appeared to be greater in the oat bran group. LDL-cholesterol was significantly lower ($p = 0.005$) in the oat bran group as compared to the group's pretreatment values. There was no significant difference in LDL-cholesterol between groups. Serum acetate values were significantly higher in the oat bran group than in the pretreatment diets. Wheat bran did not change serum acetate significantly compared to the pretreatment diets.

Kashtan et al. (Ref. 121) evaluated the effects of wheat bran and oat bran supplements on blood lipids and lipoproteins in 84 subjects with mild hypercholesterolemia. This was a controlled, parallel, double-blind study in which subjects consumed either oat bran supplements (with 11 to 17 g dietary fiber and an estimated 5 to 8 g of soluble fiber) or a wheat bran cream of wheat mixture (11 to 17 g of dietary fiber) each day for 14 days. Defined diets were delivered to the subjects' homes. The diets provided one of four energy amounts: 1,600, 2,000, 2,400, and 2,800 calories, with 37 percent of energy as fat, 47 percent carbohydrate, and 16 percent protein. Results showed mean serum cholesterol decreased significantly (-10.8 percent, $p = 0.001$) in the oat group compared to the wheat group (-4.7 percent). However, the baseline cholesterol was higher among the oat bran group. The wheat bran group also experienced significantly decreased serum cholesterol compared to their baseline ($p < 0.001$). LDL-cholesterol decreased significantly compared to baseline for both groups ($p = 0.03$ for the wheat bran group and $p < 0.001$ for the oat group). The short test period of 2 weeks in this study makes interpretation of the results difficult.

Ranhotra and coworkers (Ref. 122) studied lipidemic responses in 17 hypercholesterolemic men consuming foods high in soluble fiber. This was a 6-week intervention study with a 6-week control period prior to the test period. Subjects consumed their usual diet during the control period and kept daily records of intake for 4 weeks. Subjects were then given a list of foods that were identified as good sources of soluble fiber and a diet supplement containing 30 g each of rice bran and oat bran, and were instructed to incorporate foods on the list into their usual diet. Each subject served as his own control. Results showed that only 6 (34 percent) of the 17 subjects were responders to the soluble fiber intervention. The authors reported that not all subjects consumed the supplement daily and that intakes of soluble fiber varied greatly among the participants. Serum cholesterol values decreased from 1 percent to 17 percent compared to individual control levels in those responding to soluble fiber. However, the authors did not perform a statistical analysis of the results, and the results in this study are too inconsistent in direction and magnitude to support an effect of soluble fiber on serum cholesterol.

Zhang et al. (Ref. 123) studied the mechanism of cholesterol lowering in nine subjects with ileostomies. This was a randomized, controlled, cross-over study design. Subjects were instructed to consume their own food, which was modified to be low fiber, and were assigned to either a low fiber diet (supplemented with wheat-flour bread) or a high fiber diet (supplemented with oatbran bread) for 3 weeks followed by cross-over to the other fiber bread for another 3 weeks. Ileostomy effluents were collected on sampling days in both dietary periods. Subjects were also divided into two subgroups according to the amount of bile acids excreted in the ileostomy effluents. Results showed subjects with low bile acid excretion had significantly increased daily excretion of total bile acids on the high fiber diet as compared to the low fiber diet. There were no significant differences in daily excretion of total bile acids between the high fiber period and the low fiber period in subjects with high daily bile acid excretion. There was no baseline serum cholesterol measurement. Compared to the low fiber period, serum cholesterol and LDL-cholesterol decreased significantly ($p = 0.01$ and $p = 0.05$, respectively) in all nine subjects on the high fiber diet. Subgroup analysis showed that subjects with low daily bile acid excretions had significantly reduced serum cholesterol on the high fiber diet than on the low fiber diet. Subjects with a high daily excretion of bile acids showed no significant difference in serum cholesterol between the test periods. Conclusions about fiber mechanisms in lowering serum lipids in subjects with ileostomies may not apply to the general population.

2. Hypercholesterolemics: Step 1 or 2 diets

A study by Israelsson et al. (Ref. 86) was submitted with a comment. This placebo-controlled, double-blind, cross-over intervention study used 30 g/day beet fiber or bread. Twenty-seven hypercholesterolemic (serum cholesterol 263 to 297 mg/dL) women, 55 to 56 years old, were chosen from a CVD screening program. Subjects consumed a moderate cholesterol, low fat diet with increased polyunsaturated fatty acids/saturated fatty acids (PUFA/SFA) for a 1-month run-in period and were then randomized to the fiber group or placebo for 1 month followed by cross-over to the other diet. The beet fiber provided 6 g soluble fiber, 16.5 g

insoluble fiber, and 22.5 g total dietary fiber. Subjects decreased alcohol intake after the run-in period. No data on saturated fat or soluble fiber intakes were provided. Results showed a significant reduction in serum cholesterol in the fiber group compared to the placebo after 2 weeks, but not after 4 weeks. LDL-cholesterol showed a modest but significant reduction after 4 weeks of fiber intervention. HDL remained constant or increased significantly after 1-month intervention. The ratio of LDL:HDL was significantly reduced at the end of the test period. The short test period of this study does not address long-term effectiveness of beet fiber.

Bremer et al. (Ref. 91) evaluated the cholesterol lowering effects of oat bran and wheat bran in a randomized, single-blind, cross-over, placebo-controlled intervention trial. The fibers were incorporated into breads. Twelve hyperlipidemic men and women (total serum cholesterol 220 to 348 mg/dL) were stabilized on a American Heart Association (AHA) phase II diet (total fat 25 to 30 percent of energy, saturated fat <8 percent of energy, polyunsaturated fat 5 to 10 percent of energy, cholesterol <250 mg/day) for 3 months prior to intervention. There was a 2-week run-in prior to test during which subjects added additional bread to their diets. Subjects were randomized to one of the two fiber groups for 4 weeks, followed by 2-week wash-out, then cross-over to other fiber group. The bread (10 to 12 slices/day) was added to the diet in place of other carbohydrate foods. Subjects had a mean intake of 44.6 g/day of oat bran (range of 34.2 to 68.4 g/day). Total dietary fiber intake during the oat period was 32.2 g, and 34.1 g during the wheat period. Results showed no significant differences in total serum cholesterol or LDL-cholesterol between the oat and wheat periods. Authors account for the lack of observed response on serum cholesterol from oat bran as due to the lower soluble fiber content of New Zealand oat bran compared to oat bran used in other studies.

Anderson et al. (Ref. 92) evaluated the hypocholesterolemic effects of two bulk laxatives, relative to psyllium and a placebo (cellulose), in mild to moderately high hypercholesterolemic (total serum cholesterol 200 to 300 mg/dL) men and women. The laxatives were evaluated at the manufacturer's recommended dosages. Of the 163 subjects screened, 105 completed the 16-week study. Subjects were instructed in and consumed the AHA Step 1 diet (total fat 30 to 33 percent of energy, saturated fat 10 percent of energy, carbohydrate 46 percent of energy, cholesterol <300 mg/day) for 8 weeks followed by an 8-week parallel treatment with diets supplemented with one of three fiber supplements or placebo. Fiber sources used were the following bulk laxatives: psyllium (10.2 g/day), methylcellulose (6 or 10.2 g/day), calcium polycarbophil (4 g/day), and cellulose placebo (4 g/day). The authors note that psyllium and methylcellulose were most effective in lowering serum cholesterol. There was no significant difference between psyllium and methylcellulose in lowering serum cholesterol. Soluble fiber was not controlled in this study. Subjects on psyllium had the highest soluble fiber intake. Side effects were reported for each laxative.

An unpublished manuscript entitled "High soluble fiber foods reduce serum lipids even when diets are already low in saturated fat and cholesterol" (Ref. 93) was received as part of a comment. This 4-week, cross-over, metabolic study in 12 hyperlipidemic (mean total cholesterol of 272 mg/dL) subjects compared a psyllium cereal/low fat diet (9.35 g psyllium/day = ≤3 oz of psyllium cereal) with a similar diet substituting wheat bran for the psyllium cereal. The low fat diets were the same in both phases of the study, low in saturated fat (<4 percent of energy) and cholesterol (<50 mg/day) and high in carbohydrate (>60 percent of energy). The psyllium cereal was significantly more effective in lowering total and LDL-cholesterol than the wheat bran cereal. Mean total cholesterol reduction was from 272 mg/dL to 249 mg/dL, and from 192 mg/dL 172 mg/dL for LDL cholesterol. Preliminary subgroup analysis by the authors of the study suggested that patients with both elevated cholesterol and triglycerides (Type IIb) showed no reduction in LDL cholesterol, while patients with only Type IIa (isolated elevation of cholesterol) benefited. Additional concerns are raised by this study regarding the usefulness of psyllium in Type IIb patients.

An unpublished manuscript entitled "High fiber foods reduce serum lipids even on diets low in saturated fat and cholesterol" (Ref. 94) was received as a comment. This was a cross-over study with 11 hyperlipidemic volunteers. Each 16-week test period was separated by a 2-month wash-out period during which subjects consumed only the Step 2 diet (total fat <20 of energy, saturated fat <7 percent of energy, cholesterol <100 mg/day, and carbohydrate >60 percent of energy). During one metabolic phase, subjects were fed foods considered good sources of soluble fiber (e.g., legumes and psyllium-containing cereals) as part of the Step 2 diet. During the second phase, wheat bran-containing foods were fed. Results showed that both the soluble- and insoluble-fiber groups lost weight during the 4-month test period. The insoluble-fiber group lost significantly more than the soluble-fiber group. Although, blood lipids fell on both diets, total cholesterol, LDL- and HDL-cholesterol values were significantly lower (6.3 percent, 8.6 percent, and 5.7 percent, respectively) in the soluble-fiber group than in the insoluble-fiber group. The soluble fiber diet emphasized foods shown in other studies to reduce serum cholesterol, i.e., dried beans, peas, other legumes, oat bran, and a psyllium-containing cereal. The actual difference in soluble fiber content between the soluble and insoluble fiber diets was only about 3.2 g/day, on average. The authors felt that the specific foods they fed contribute to lowering of serum cholesterol, but expressed concern that not all soluble fibers show this effect, and that no mechanism of action is apparent. They, therefore, expressed "concern over lipid lowering claims for direct dietary fibers."

An intervention study by Anderson et al. (Ref. 95) with 44 hyperlipidemic (serum cholesterol 200 to 300 mg/dL) men and women was conducted using a randomized, double-blind, and parallel design. Subjects consumed a Step 1 diet and 3.7 ounce (oz)/day (on average) of either a wheat bran cereal or a psyllium cereal for 6 weeks. The psyllium cereal provided 10.7 g/day of psyllium. The psyllium group had a lower total cholesterol by about 8 percent and LDL cholesterol by nearly 13 percent by the end of the study. Mean total cholesterol, however, was still higher than 200 mg/dL despite these reductions. Both groups had comparable weight loss of about 1 (lb) pound. Because this study had a short test period, it did not address the long-term usefulness of psyllium in reducing serum cholesterol. In a parallel design, nonblinded clinical trial with 59 men and women with total cholesterol between 215 and 396 mg/dL, Neal and Balm (Ref. 98) placed all subjects on Step 1 diets for 7 weeks. The control group continued on the Step 1 diet, and the test group received 20.4 g of psyllium per day in the form of Metamucil immediately after breakfast and the evening meal for 13 weeks. After the treatment period, the psyllium group had a decrease in total cholesterol of 7.1 percent, while the control group had a 1.6 percent decrease. The difference between the test and control

groups was 5.5 percent, a significant decrease. Although there was a 5.1 percent decrease in LDL in the psyllium group compared to the control, this decrease was not significant. The authors failed to report the amounts of total fat, saturated fat, and total soluble dietary fiber consumed during each period.

Two short-term studies by Wolever et al. (Refs. 101 and 102) evaluated the effectiveness of psyllium in lowering serum cholesterol (Ref. 101) and its effectiveness when psyllium was taken with meals or between meals (Ref. 102). These studies were done with men and women, some of whom were on lipid-lowering drugs, who were instructed on a Step 2 diet. The test periods were for 2 weeks. In both studies, serum cholesterol was lowered significantly at the end of the 2 weeks.

O'Connor et al. (Ref. 103) conducted a well-controlled multicenter, double-blind randomized, parallel group, placebo-controlled trial with men and women between the ages of 18 and 70 years with a diagnosis of mild to moderate primary hypercholesterolemia (see Table 1). A five fiber supplement, containing guar and pectin and providing 7.5 g of soluble fiber and 2.5 g of insoluble fiber, was administered either once or twice a day for 15 weeks with a Step 1 diet. The placebo group received 5.2 g of insoluble fiber with no soluble fiber before breakfast and dinner. All nutrients were kept constant except for fiber. Serum cholesterol and LDL-cholesterol were significantly reduced compared to placebo in all studies (see Table 1, studies B301 and B302 in). An extension of this study evaluated the long-term usefulness of the five fiber supplement for an additional 36 weeks (total of 51 weeks). Significantly reduced levels of total and LDL-cholesterol were maintained (5.3 percent and 8.4 percent, respectively) compared to baseline. This study shows both the ability of a particular soluble fiber product for reducing blood lipids and the long-term benefits of soluble fiber supplementation with a low fat diet.

An unpublished study (Ref. 108) evaluated the hypocholesterolemic effect of psyllium in 23 hypercholesterolemic men (mean total cholesterol greater than 240 mg/dL). Using a double-blind, double cross-over design, the subjects were randomly assigned to either the psyllium-wheat bran-psyllium group or to the wheat bran-psyllium-wheat bran group for 8, 5, and 5 weeks, respectively. Subjects consumed a total of 10 g of soluble fiber/day from psyllium and 2 g of soluble fiber per day from wheat bran. All subjects consumed a Step 1 low fat diet as the base diet. Results showed significant cholesterol and LDL-cholesterol lowering (4.3 percent) with psyllium compared to the wheat phase of the test. Initial cholesterol values for each group were not given.

A 1987 study by Turnbull and Leeds (Ref. 111) was submitted with comments from the food industry as further evidence for a hypocholesterolemic effect of soluble fiber from oat bran. In this study, 17 free living men and women aged 23 to 73 years (serum cholesterol levels above 232 mg/dL) were given varying degrees of instruction on a low fat diet (<35 percent calories from fat). All subjects followed this diet for a 1-month run-in period. Eight subjects were followed intensively during the run-in period and fiber periods through blood sampling and diet histories. Subjects were then randomly assigned to receive either 150 g/day oats (from cereal and muffins) or 100 g/day wheat flour biscuits for 1 month followed by cross-over to the other fiber diet for an additional month. The oat products provided 5.4 g of soluble fiber per day. The wheat products provided 3.1 g/day. Results during the run-in period showed a significant loss of weight and reduction in serum cholesterol in the group of eight subjects studied intensively during the first month. At the start of the first test period (whether oat or wheat) all subjects had a mean fat intake of 34 percent of calories. During the oat period, the subjects' energy intakes increased and fat intake increased to 35 percent. Mean body weight, however, remained constant. Combining all results from the oat-wheat and wheat-oat periods, serum- and LDL-cholesterol fell significantly ($p = 0.02$ and $p = 0.003$, respectively). During the wheat period, the subjects' caloric intake increased with a mean body weight increase of 0.3 kilogram (kg). Total fat consumption during the wheat period was 36 percent of calories. Mean serum cholesterol of the combined period showed a nonsignificant increase (1.6 percent) in serum cholesterol during the wheat period. LDL-cholesterol showed a nonsignificant increase. In the eight subjects followed intensively throughout the study, the results showed that most of them had further reductions in total and LDL-cholesterol on the oat diet beyond the low fat diet alone. In a later study (Ref. 126) of the same design and using the same levels of oats and wheat flour, the authors reported favorable changes in apolipoprotein A1 and no change in apolipoprotein B in subjects on the oat diet.

The purpose of the study by Fukagawa et al. (Ref. 114) was to evaluate the effects of a very high carbohydrate high fiber (HCF) diet on peripheral-tissue insulin responsiveness in a group of healthy young men (ages 18 to 24 years, Group A) and in a group of older men and women (ages 67 to 86 years, Group B). The young men had normal serum cholesterol (199 mg/dL) and the older adults were hypercholesterolemic (237 mg/dL). The subjects were studied while consuming their usual ad libitum diet and after consuming a HCF diet for 21 to 28 days. The older group was admitted to the metabolic ward for the duration of the study. The younger subjects only ate their meals on the metabolic ward. The study was not blinded or placebo controlled. Test diets provided the following: Group A— 23.6 g/day soluble fiber, 88.2 g of plant fiber/day, 134 mg dietary cholesterol, 14 percent energy as fat, 3 percent energy as saturated fat, 69 percent of energy as carbohydrates; Group B— 17 g of soluble fiber, 67.7 g of plant fiber/day, 90 g of dietary cholesterol, 15 percent energy as fat, 3 percent energy as saturated fat, and 70 percent energy as carbohydrates. Results showed a significant reduction in serum cholesterol in both groups after 4 weeks (Group A: 26 percent; Group B: 45 percent). The results of this study are inconclusive for an effect of fiber on serum cholesterol (which was not the objective of the study) because the subjects' ad libitum diets were significantly higher than the test diet in fat (37 to 42 percent of calories compared to approximately 14 percent on the test diet), saturated fat (15 to 17 percent of calories versus 3 percent of calories), and lower in carbohydrates (40 to 45 percent of calories versus 68 to 70 percent of calories). In addition, there was no control group.

Anderson et al. (Ref. 118) evaluated the cholesterol-lowering benefits of psyllium-enriched cereal in subjects with mild to moderate hypercholesterolemia (serum cholesterol range of 200 to 300 mg/dL). Subjects consumed their usual diets for 1 week before being randomly assigned to receive psyllium-flake or wheat bran flake cereal for 6 weeks. Subjects were also instructed on a Step 1 diet and asked to adhere to it for 6 weeks. Soluble fiber intake during the treatment period was 5.9 g per day for the wheat bran group and 15.1 g/day for the psyllium group. Results showed significantly reduced serum- and LDL-cholesterol in the psyllium group compared to the wheat group. Serum

cholesterol was reduced 8.36 percent (p = 0.01) and LDL-cholesterol 12.9 percent (p = 0.01) in the psyllium group. There was no significant change in serum- or LDL-cholesterol in the wheat group.

3. Normocholesterolemics: "typical" or "usual" diets

Resnicow et al., 1991 (Ref. 96), measured total serum lipids in a population of 31 Seventh Day Adventists, ages 5 to 46 years, who had consumed a pure vegetarian diet for at least 6 months prior to taking of blood samples. Diets of vegans were compared to those of omnivore controls. Blood samples were not taken from the controls and blood values for these subjects were derived from the Lipid Research Clinics Population Studies Data Book. Results showed that the adult vegans consumed significantly less energy and energy from fat (31 percent versus 38 percent of calories), total fat, saturated fat, monounsaturated fat, cholesterol, and protein. They also consumed significantly more fiber (45 g/day versus 20 g/day) than the omnivores. Total dietary soluble and insoluble fibers were not assessed. Foods consumed in greater frequency by vegans included almonds, cashews, and their nut butters, dried fruits, citrus fruits, soy milk, and greens. Total serum cholesterol for vegans was approximately 23 percent lower (139 mg/dL versus 182 mg/dL) than expected values for omnivores.

One study submitted with comments evaluated the effect of glucomannan, a pectin-like gel fiber derived from purified tubers of *Amorphophallus koniac* K. Koch, on serum cholesterol and weight reduction in obese patients consuming their normal diets (Ref. 117). Weight loss and serum cholesterol decreased significantly in the test group compared with the placebo group at the end of the 8-week trial. After 4 weeks on the test product, subjects had a mean weight loss of 4.9 lb and mean serum cholesterol reduction of 20.9 mg/dL. After another 4 weeks, weight loss was only 0.6 lb and serum cholesterol was reduced only 0.8 mg/dL. Because weight loss and serum cholesterol are closely correlated, the effect of glucomannan on serum cholesterol cannot be determined from this study.

An unpublished study studied the mechanism of serum cholesterol reduction by oat bran (Ref. 124). This was a 2-month metabolically-controlled intervention trial with nine normocholesterolemic men. A single isotope was used to determine bile acid kinetics during the oat bran period. During the first month, subjects consumed a constant diet provided in a metabolic unit. The fat content of the diet was 35 percent of the energy. The total soluble fiber content of the low fiber diet ranged from 3.0 to 4.9 g/day and for the high fiber period 9 to 12 g/day. During the second month, this same diet was supplemented with 100 g of oat bran per day. Results showed significantly lowered serum cholesterol during both periods. Serum cholesterol was 14 percent lower compared to the prestudy period during the low fiber period and 22 percent lower during the high fiber period. Serum cholesterol during the high fiber period was also significantly lower than that of the low fiber period (an additional decrease of 9 percent). Bile acid excretion approximately doubled during the high fiber period.

4. Normocholesterolemics: low fat diets

Nervi et al. (Ref. 107) reported than an intake of 120 g/day of legumes for 30 to 35 days significantly lowered serum cholesterol (from 162 to 143 mg/dL) in 20 Chilean young men compared to responses of men on a control diet. The men consumed beans, peas, or lentils each day as part of a diet that provided 33 percent of calories from fat and 12.5 g of total fiber. The study was designed to evaluate the hypothesis that legumes may be a risk factor for cholesterol gallstones in certain subpopulations. The authors reported significantly increased biliary cholesterol saturation and modification of bile acid composition during the legume diet period.

5. Other studies

Evidence for the cholesterol-lowering effect of soluble fiber from oats was evaluated using meta-analysis (Ref. 125). In this study, after pooling the raw data from 5 investigators who had looked at the effect of consumption of oat products on blood total cholesterol, a modest reduction (average decrease of 5 to 6 mg/dL) on blood total cholesterol levels was found. The decrease in blood total cholesterol was largest in those trials with initially higher blood total cholesterol levels, particularly where an intervention dose of 3 g or more of soluble fiber from oats was used. To assess whether other dietary factors, i.e., dilution of saturated fat and calorie intakes by the oatmeal or oat bran addition to diets, might have been responsible for the drop in blood total cholesterol levels, the authors used the experimentally derived, predictive equation of Keys to see if dietary changes in fat components of the test diets could account for the observed decreases in serum cholesterol. The fat and saturated fat changes did not appear to be responsible for the drop in serum cholesterol levels, thus suggesting that some other factor in the test diets (e.g., the soluble fiber fraction) was responsible for the observed effects. The authors concluded, therefore, that incorporation of oats (a rich source of soluble fiber, primarily as β-glucan) into diets causes a modest decrease in average blood cholesterol. The authors also suggested that there was a dose-response relationship between the amount of soluble fiber from oats and the reduction in blood cholesterol levels, with intakes of soluble fiber from oats above 3 g/day showing more effect than lower intakes. Additionally, the authors noted that other components in oats may play a role in the observed cholesterol reduction and suggested the need for long-term clinical trials (6 months or more) with multiple doses to verify their conclusions from the meta-analysis.

6. Summary of human studies

The human studies reviewed above suffered from many of the same design flaws noted in the proposed rule on health claims for dietary fiber and cardiovascular disease (56 FR 60582 at 60591). Some studies were conducted with very small sample sizes (Refs. 84, 85, 87, 90, 91, 93, 94, 97, 110, 111, 114, 122, 123, 124, and 126). Another limitation was short study times (Refs. 87, 101, 102, 110, 114, 120, 121, and 123). Inadequate control of confounding factors, such as concomitant weight losses and changes in other dietary components which may have affected results, plagued some studies (Refs. 86, 96, 107, 108, 110, 117, 119, and 120). The absence of adequate dietary intake data to assure that dietary changes other than differences in soluble fiber intakes had not occurred was a problem for a number of studies (Refs. 84, 86, 87, 88, 90, 91, 95, 97, 99, 105, 106, 119, and 123).

Several studies were suggestive of positive effects of soluble fiber intakes on blood cholesterol levels. One study provided evidence of a relationship between consumption of foods high in soluble fiber and reduced levels of blood total- and LDL-cholesterol levels (Ref. 118). In a comparison of a breakfast cereal fortified with psyllium, a rich source of soluble fiber (12 g of psyllium/day from 114 g/day of a psyllium-containing cereal) to a wheat bran cereal which contributed negligible amounts of soluble fiber, the psyllium-containing cereal was associated with lower blood total- and LDL-cholesterol levels after 6 weeks than were observed in subjects following a diet containing wheat bran

cereal. In another study (Ref. 104), consumption of 123 g of oat bran cereal (contributing 10.3 g soluble fiber daily) versus consumption of 54 g of wheat bran cereal per day (contributing 3.4 g of soluble fiber daily) was associated with lower blood total- and LDL-cholesterol levels after 4 weeks. Dietary intakes of fat and saturated fat were estimated to be similar across treatments. On the other hand, some studies found no relationship between intakes of high soluble fiber diets and blood total- or LDL-cholesterol levels (Refs. 83 and 91). Several explanations for the lack of a relationship in these studies were offered by the authors, including the possibility that the oat bran used was low in soluble fiber content (Refs. 83 and 91). The study by Neal and Balm (Ref. 98) showed significantly lower blood total-cholesterol levels with consumption of a psyllium-fortified cereal, but the decline in LDL-cholesterol levels compared to the control was not statistically significant. A small body weight loss in both groups may have confounded the relationships. However, since it is the LDL-cholesterol, rather than the total-cholesterol, that is the desired endpoint for evaluating beneficial changes, the lack of statistical significance for serum LDL-cholesterol levels limits this study's usefulness.

Finally, the meta-analysis on the cholesterol-lowering effect of oat products was useful and suggested a benefit from oat consumption. However, the authors noted that, while grams of soluble fiber were chosen to represent the dose of oat product, it is entirely possible that other components of oats, as well as the way in which the oat product is prepared, may also play a role in reduction of blood LDL-cholesterol levels. The authors recommended that, because there are several components of oats which could provide beneficial effects on blood cholesterol levels, future clinical studies should test multiple doses of oat products with the simultaneous measurement of other possible active components, including soluble fiber, β-glucan, and tocotrienols.

The most definitive results linking soluble fiber intakes to beneficial changes in blood cholesterol levels were for studies in which dietary supplements of guar (Refs. 99 and 100), gum arabic (Ref. 109), psyllium (Ref. 92), or a combination of soluble fiber sources (Ref. 103) were given. Some of these studies (Refs. 99, 100, and 109) also, however, failed to provide adequate information on dietary intakes, thus limiting the ability to rule out possible confounding effects from other dietary changes that may have occurred concomitantly with addition of these supplements. A series of well-conducted clinical trials were done to design and test the effectiveness of fiber mixtures (guar, pectin, psyllium, and locust bean) on blood cholesterol levels (Refs. 103 and 106). Early studies in one series (Ref. 106) showed no benefit from acacia gum alone or a mixture of acacia gum, psyllium and guar (Studies 1 and 2). Only when a mixture of pectin, psyllium, guar and locust bean was given were beneficial effects seen (Study 4). These results strongly suggest that benefits of fiber supplements are not readily predicted by an analytical definition of soluble fiber, but rather vary, in some unknown way, among different sources or combinations of sources, of soluble fiber. Thus, generalizing results from one fiber source to another must be done cautiously.

B. Animal studies submitted with comments

FDA received a number of animal studies submitted as comments. FDA has reviewed these studies as described below.

1. Relationship between specific soluble fibers and plasma cholesterol

Ney et al. (Ref. 127) evaluated the effect of soluble oat fiber on blood very low density lipoprotein (VLDL), low density lipoprotein (LDL), and high density lipoprotein (HDL) levels by feeding male rats cholesterol-raising diets (diets which contained 1 percent cholesterol and 0.2 percent cholic acid as the stimulus for increasing blood cholesterol levels) and 6 percent dietary fiber from cellulose (control) or from three oat products with increasing levels of soluble fiber: Oat bran, high fiber oat flour or a processed oat product. Compared to the cholesterol-fed cellulose control, all oat fibers lowered plasma total cholesterol by 25 to 45 percent, lowered VLDL + LDL cholesterol levels by 40 to 60 percent, and raised HDL-cholesterol by 25 to 40 percent (all significant at $p = 0.01$). This pattern of changes in blood lipid components is associated with decreased risk of heart disease. The processed oat product, which contained 40 percent more soluble fiber than oat bran or oat flour, resulted in a lipoprotein profile similar to that obtained without the cholesterol-raising stimulus of dietary cholesterol and cholic acid. The oat product with the highest soluble fiber content was, therefore, more effective with ingestion of the cholesterol-raising diet than was the oat bran or oat flour with lower amounts of soluble fiber. The authors suggested that these data, which show greater benefits as the soluble fiber content increases, support the suggestion that soluble fiber is the component of oat fiber responsible for the cholesterol-lowering effect of oat-containing diets.

Nishini et al. (Ref. 128) evaluated the effect of dietary fibers from oat bran, wheat bran, cellulose, and pectin on plasma lipoproteins, apolipoproteins and enzymes involved on cholesterol metabolism in non-fasted rats. The animals were fed experimental diets estimated to contain 8 percent dietary fiber by weight. Results showed that pectin-fed animals (i.e., animals receiving the highest soluble fiber) had significantly lower serum cholesterol, HDL-cholesterol, and apolipoprotein A-1 levels compared to the fiber-free control. Total cholesterol levels in the wheat-bran-fed (primarily insoluble fiber) or oat bran-fed (mixed soluble/insoluble fiber) animals were not significantly different from the fiber-free control. No data were given on the soluble fiber content of the diets, although the pectin diet would be expected to have the highest level of soluble fiber. Results showed that blood lipid distributions are affected differently by dietary fibers, and that changes among lipid components frequently occurred without a change in overall cholesterol concentrations.

Prentice et al. (Ref. 129) compared the effects of ground and rolled caryopses of barley and rolled oats to ground corn on hepatic cholesterol and fatty acid synthesis in chickens. Approximately 7 to 8 percent of the barley and oat cereals was β-glucan; corn had less than 1 percent β-glucan. Both barley and oats decreased plasma total cholesterol by 32 percent and 25 percent, respectively. The authors attributed the effect on serum cholesterol to the higher soluble fiber content of barley and oat diets.

Summaries of unpublished animal studies (Ref. 130) suggested that oats may be effective in lowering plasma cholesterol compared to controls fed white flour, wheat flour, or corn starch. However, the data were preliminary and, thus, had limited usefulness.

Other summaries of unpublished animal studies (Ref. 136) suggested that rolled oats (75 percent by weight in diet) significantly lowered serum cholesterol in chicks. Extruded oat bran, equivalent to 47 percent of oat bran by weight in the diet, significantly depressed ($p = 0.05$) serum cholesterol in chicks. Oat gum at 0.05 percent and 0.10 percent by weight in the diets of rats significantly lowered serum cholesterol. Data comparing several oat fractions fed to chicks suggested that oat gum may be

the active cholesterol depressant component, and that ground rolled oats and instant oatmeal are equal in effect to the defatted, defibered oat flour. The oat oil also had a depressive effect. Additionally, pectin (high soluble fiber) was found to significantly lower serum cholesterol in rats. These studies were done in the mid-1970's and did not have analyzed values for soluble fiber content of the respective diets. Methods and data were not well described, making results difficult to interpret.

Qureshi et al. (Ref. 131) reported the effects of diets supplemented with either corn (61.5 percent by weight of the base diet), wheat (75 percent of the diet), barley (73.5 percent), oats (74.5 percent), or rye (73.5 percent) on serum cholesterol in chickens. This was part of a study to investigate the effects of dietary cereals on the metabolic regulation of lipid metabolism in chicken livers. Compared to corn, barley and oats lowered serum cholesterol 45 percent and 32 percent, respectively. Presumably, barley and oats were higher in soluble fiber content than was corn. However, no fiber content data were presented. Additionally, body weights for animals consuming the barley and oats diets varied, making it difficult to ascribe the effects to fiber per se.

Ranhotra and co-workers (Ref. 132) evaluated the effect of oat bran and oat bran concentrate on serum lipids in rats. Animals were fed experimental diets containing oat bran (5.57 percent soluble fiber) or oat bran concentrate (13.75 percent soluble fiber). Results showed the high soluble fiber content of the oat bran concentrate was associated with a significantly lower serum cholesterol level, but that the oat bran diet (which contained lower amounts of soluble fiber) and the diet free of soluble fiber were not associated with lower serum cholesterol levels.

Shinnick et al. (Ref. 133) evaluated the ability of various sources and forms of oat fiber to lower plasma and liver cholesterol in male rats fed a diet with 6 percent dietary fiber as cellulose (0 percent soluble fiber), oat bran (7 percent soluble fiber), high fiber oat flour (8 to 10 percent soluble fiber), or one of four processed high fiber oat flours (8 to 12 percent soluble fiber). All diets were supplemented with 1 percent cholesterol and 0.2 percent cholic acid to stimulate increased levels of blood total cholesterol. Results showed that all oat products significantly lowered serum cholesterol compared to the control. In a second experiment, diets containing 4 percent dietary soluble fiber in a processed oat flour significantly lowered serum cholesterol. The processed oat flours had higher soluble fiber fractions than the less processed oat products.

In a study published in 1983, Rogel and Vohra (Ref. 135) reported no effect from five varieties of oats (oat bran or oat hulls) fed for 4 weeks on the serum cholesterol levels of quail. No data on soluble fiber were given.

Kritchevsky et al. (Ref. 138) evaluated the cholesterol-raising effects of oat and wheat bran on blood cholesterol levels in rats in a three-week feeding study in which semipurified diets containing 0.5 percent cholesterol and 10 percent oat bran, wheat bran or cellulose were fed to male rats. Weight gains varied among the diets. Results showed that, under these study conditions, there were no effects of diet on any of the serum lipids. No data on soluble fiber content of the diets were provided.

Kahlon et al. (Ref 140) evaluated the effects of rice brans (full-fat or defatted), oat bran, or rice-wheat bran combinations on cholesterol in hamsters. The control diet contained 10 percent cellulose and 0.5 percent cholesterol. Test diets were composed of the control diet plus one of the brans. The oat bran contained 8 percent dietary soluble fiber versus 2 to 3 percent soluble fiber in the other brans. Results showed that rice bran (with fat) and oat bran resulted in significantly lower plasma cholesterol than the control diet. Defatting rice bran resulted in loss of its cholesterol-lowering properties, suggesting that it is the lipid portion rather than the fiber portion of rice bran which is responsible for its cholesterol-lowering effects.

In another study, rats were fed a diet containing 1 percent cholesterol and 0.2 percent cholic acid with added cellulose, oat gum, chitosan, or cholestyramine (5 percent of the diet). Cholestyramine, oat gum, and chitosan all significantly lowered blood and liver cholesterol levels, with the greatest effect with cholestyramine, a commonly used cholesterol-lowering drug. Oat gum, at 5 percent of the diet, reduced serum cholesterol by 23 percent (Ref. 141).

Forsythe et al. (Ref 142), in a study published in 1978, evaluated the influence of source and particle size of dietary fibers on hypocholesterolemic effects in rats. The sources of fiber were cellulose, wheat bran, wheat midlings, oat bran, oat flour, sugar beet pulp, soybean hulls and psyllium seeds. There were significant differences in weight gain and food intake among dietary treatments. No fiber decreased serum cholesterol compared to the fiber-free group.

Significantly lower values of plasma total cholesterol and liver cholesterol in rats fed fiber sources known to contain soluble fibers (oat bran, oat gum, and pectin) compared to rats fed cellulose (insoluble fiber) were reported by Chen et al. (Ref. 143). Rats were fed a base diet containing 1 percent cholesterol and 10 percent by weight of one of the four fiber types. The greater effect of oat gum compared to oat bran was interpreted by the authors to suggest that the plasma and liver cholesterol-lowering effects of oat bran are due to its gum fraction.

Chen and Anderson (Ref. 144) examined the effects of fiber-supplemented diets on total and LDL-cholesterol in rats. Rats were fed one of five experimental diets containing sucrose and 10 percent plant fibers. The diets were as follows: sucrose and cellulose, sucrose-cholesterol with cellulose, sucrose-cholesterol-pectin, sucrose-cholesterol-guar gum, and sucrose-cholesterol-oat bran. Results showed that fiber-fed rats had significantly lowered plasma cholesterol than rats that received cellulose; the lowest concentrations were observed in the pectin-treated group. No data were given on the soluble fiber content of the test diets, although the pectin would presumably contain the highest concentration of soluble fiber.

Chen and Anderson (Ref. 146), in two experiments, examined the effects of guar gum or wheat gum on the plasma and liver lipid levels of rats. In the first experiment, animals were fed one of three diets for three weeks: diet plus sucrose and 10 percent cellulose; sucrose, 15 percent wheat bran, and 4 percent cellulose; and sucrose and 45 percent wheat bran. Each diet provided 10 g of plant fiber. In experiment two, animals were fed one of four diets: diet plus sucrose, sucrose plus cholesterol, sucrose plus cholesterol and wheat bran, or sucrose, cholesterol, and guar gum. The wheat and guar diets provided 7 g of plant fiber; the other two diets provided 4 g of plant fiber. Results from experiment 1 showed that the two wheat bran diets (high in insoluble fiber) significantly raised plasma cholesterol compared to the control. Results of experiment 2 showed the guar diet (high in soluble fiber) significantly lowered serum cholesterol compared to those fed the sucrose-cholesterol or sucrose-cholesterol-wheat bran diets. Plasma cholesterol was similar between the sucrose-cholesterol and wheat groups.

Wilson et al. (Ref. 148) examined the influence of different soluble fibers upon the metabolism of lipids in genetically hyperlipemic, obese Zucker rats. Four diets were tested: a non-fiber diet (no added fiber), a 0 percent soluble fiber diet (cellulose fiber), an oat bran

diet (33 percent soluble fiber), and a pectin-citrus fiber diet (100 percent soluble fiber). Except for the control, the fibers provided 10 percent of the total diet weight. Results showed non-significant decreases in total plasma cholesterol in the oat bran and pectin groups compared to the no-fiber and cellulose groups. However, the pectin group (the highest soluble fiber group) had changes in blood lipid components associated with reduced risk of heart disease: significantly lower LDL-cholesterol and significantly higher HDL-cholesterol.

Welch et al. (Ref. 149) evaluated the hypocholesterolemic effects of oat bran fractions. Oat bran was separated into five fractions: oil, insoluble fraction (rich in starch and insoluble fibre), protein-rich, oat gum, and soluble residue. These were fed to chicks. Results showed that, compared to the control, only the diets containing oat bran, oat gum, or the protein fractions significantly lowered plasma cholesterol. Oat gum was the only fraction which had the same effect in reducing plasma cholesterol levels as did the native oat bran. Thus, oat gum was concluded to be the main cholesterol-lowering component of oat bran. Beta-glucan was the main component of the gum fraction. However, the protein fraction also had a beneficial effect on plasma cholesterol levels, although of a lesser magnitude than the gum portion.

Five sources of dietary fiber were compared for their effect on blood and liver cholesterol in beef-fed C57BL/6 male mice (Ref. 150). Mice were fed one of the following fiber supplements (7 percent dietary fiber) with the experimental diet: soybean fiber, rice bran (full fat), oat bran, barley bran, and mixed bran (one-third each of rice, barley, and oat brans). Results showed significantly lower plasma total cholesterol compared to the control in the rice bran and soybean fiber groups.

Ginter et al. (Ref. 151) reported that addition of 5 percent citrus pectin (a high soluble fiber source) and 0.5 percent ascorbic acid to a high-fat diet fed to guinea pigs prevented cholesterol accumulation in blood serum and the liver.

Kakis et al. (Ref. 152) reported reduced serum cholesterol and HDL levels in all psyllium-fed (a soluble fiber) animals as compared to wheat bran-fed (a relatively high insoluble fiber source) animals after a three week experimental period. Relative to the appropriate wheat bran control, psyllium had a graded serum hypocholesterolemic effect that varied from a high of 41 percent at low dietary cholesterol concentrations to 26 percent at high dietary cholesterol concentrations. However, HDL cholesterol (in mg percent and as a percent of total cholesterol), the "beneficial blood cholesterol," was lower in the psyllium groups than in the respective wheat bran controls. Thus, the overall benefit of psyllium was not clear from this study.

Life Sciences Research Office's (LSRO) 1982 report to FDA on the health aspects of psyllium seed and other food ingredients (Ref. 153) was submitted with comments. Summaries of studies with beagles fed psyllium-supplemented diets consistently showed lowered serum cholesterol compared to controls.

2. Animal studies: dose-response relationship between soluble fiber and plasma cholesterol

Shinnick et al. (Ref. 134), following evaluation of several approaches to improve the cholesterol-fed rat model used to evaluate the hypocholesterolemic potential of foods, fed nine levels of a high fiber oat flour (HFOF) derived from oat bran to male Sprague-Dawley rats. Ingestion of increasing amounts of HFOF, containing 0 to 10 percent dietary fiber, by rats in which high blood cholesterol levels had been produced with 1 percent cholesterol and 0.1 percent cholic acid, resulted in a significant inverse relationship between serum cholesterol levels and HFOF intake for serum and liver cholesterol levels. Similar results were obtained for liver cholesterol levels. The authors suggested that, although this study does not distinguish among the components of HFOF that may contribute to the cholesterol-lowering effect, the observed dose-response relationship in the rat model is suggestive that larger intakes of soluble oat fiber sources may be accompanied by greater reductions in serum cholesterol levels in humans.

Turley and co-workers (Ref. 147) conducted a dose-response study to three levels of psyllium supplementation in the diets of hamsters. Results were compared to two other nonabsorbable polymers known to have cholesterol-lowering effects (i.e., cholestyramine and surfomer). Animals were fed diets containing 0 percent, 1 percent, 4 percent, or 7.5 percent psyllium. Results showed significantly lowered plasma cholesterol compared to the control group in animals consuming 4 percent and 7.5 percent psyllium. The group consuming 7.5 percent psyllium had the lowest plasma cholesterol, although the authors did not report any significant difference between the 4 percent and 7.5 percent psyllium groups. While all three polymers were effective in reducing plasma total and LDL-cholesterol levels, each exerted different quantitative and qualitative effects on bile acid and cholesterol metabolism, suggesting that mechanisms of action may vary by fiber type.

3. Animal studies: relationship between β-glucan and plasma cholesterol

Three cultivars of hull-less barley containing β-glucans were evaluated for their hypocholesterolemic responses in chickens (Ref. 137). The authors identified the Arizona cultivar of barley as a waxy-starch genotype of high molecular weight and with a high β-glucan content. The Washonupana cultivar was second highest in molecular weight and is also described as a waxy-starch type genotype. The third cultivar, Franubet, has the lowest molecular weight and is not waxy in texture. These latter two genotypes have normal β-glucan contents. Both the Arizona and Washonupana varieties produce highly viscous slurries in water, and this viscosity was greatly reduced by addition of the enzyme, endo-β-glucanase, which destroys the β-glucan. Results of feeding studies in rats showed that both the Arizona and Washonupana cultivars reduce serum cholesterol in chickens. The Franubet variety had no effect. The authors interpreted these results to mean that the cholesterol-lowering properties of the Arizona and Washonupana cultivars were probably a function of their viscous β-glucan content.

Klopfenstein and Hoseney (Ref. 139) evaluated the cholesterol-lowering effect of β-glucan-enriched bread. Oat, barley, wheat, and sorghum breads were made with and without β-glucan from each type of grain (e.g., oat β-glucan was processed into oat bread) and fed to rats for 35 days. Breads containing β-glucans from oats and barley adversely affected weight gains and feed efficiencies. Results showed lowered serum and liver cholesterol in rats fed the β-glucan-enriched bread than those fed the control breads. Given differences in weight gains, results are difficult to interpret.

Fadel et al. (Ref. 145) evaluated the hypocholesterolemic effects of β-glucans in different barley diets fed to chickens and the influence of β-glucanase on the hypocholesterolemic effects. The animals were divided into five groups and fed one of five diets: a corn-diet, Washonupana (WSNP) barley, WSNP with β-glucanase, Fraubet (FNBT) barley, FNBT with β-glucanase. Results showed significantly lowered serum

cholesterol only in chicks fed the WSNP diet. LDL-cholesterol levels for all barley fed chicks were significantly lower than that of the corn diet-fed chicks. Only the WSNP fed chicks had serum cholesterol significantly lower than WSNP fed chicks with supplemental β-glucanase. There was no significant difference in total cholesterol in FNBT and FNBT plus supplemental β-glucanase fed chicks. β-glucan in the Washonupana barley has hypocholesterolemic effects and addition of the β-glucanase to this diet reverses the hypocholesterolemic effects. However, the lack of similar finding with added β-glucanase to the Franubet variety suggests that β-glucans may differ among different varieties.

4. Summary of results from animal studies

The animal studies received as comments, and reviewed above, provide evidence to support the likely effectiveness of soluble fibers relative to the cholesterol-lowering characteristics of diets high in some cereals. However, the animal studies, like the human studies, fail to provide adequate specifications characterizing the test fiber sources. Indeed, similarly to many human studies, many animals studies did not analyze experimental diets for soluble fiber content, nor provide descriptions of the physical characteristics or commercial sources of the soluble fibers used as test substances.

Results from the animal studies showing effectiveness of increasing levels of oat products are suggestive, but not conclusive, evidence of a dose response for soluble fiber (Refs. 127, 132, 134). A specificity for the gum portion of oats, the major source of soluble fiber in oats—and specifically, of beta-glucan as the predominant soluble fiber source—is suggested by several studies (Refs. 127, 129, 132, 134, 137, 141, 143, 145, and 149). However, the solubility (and possibly, the effectiveness) of beta-glucan is apparently variable, and can be affected by such factors as plant variety (Refs. 137 and 145), or food processing such as baking of bread (Ref. 154). These results, therefore, suggest that analysis of the beta-glucan content per se may not be sufficient to characterize the active soluble fiber content of foods.

Other soluble fibers were also shown to have serum cholesterol-lowering effects in animals, including pectins (Ref. 128, 143, 144, 148, and 151), psyllium (Refs. 147 and 152), and guar gum (Ref. 146). However, in the psyllium study (Ref. 152), adverse effects on HDL-cholesterol levels were observed, raising the issue that individual fibers need to be evaluated as to their overall effect on all relevant blood lipid components, not simply limited to blood total or LDL-cholesterol levels. The various fiber sources also appear to have different mechanisms of action and different relative magnitudes of effect (Refs. 128 and 147), thus suggesting that caution is necessary before generalizing from one type of dietary fiber to another.

C. Conclusions from new studies

FDA reviewed over 40 human studies that became available since publication of its proposed rule, and a number of animal studies submitted as comments. The most commonly studied soluble fiber sources were oat bran, pectin, guar gum, and psyllium. Other fibers studied were wheat germ, beet fiber, and gum arabic. A few studies evaluated the effects of mixtures of soluble and insoluble fibers or food sources of soluble fibers.

FDA evaluated results from these studies in light of studies reviewed in the proposal and conclusions from Federal government and other authoritative reviews. In the proposal, FDA noted that, although most reviews by authoritative scientific bodies had concluded that diets rich in water-soluble fiber fractions were associated with cholesterol-lowering effects in humans, it was not possible to conclude that the observed effects were due to the soluble fiber or to other components associated with consumption of foods rich in soluble fiber. FDA also noted that there was some evidence that different types of soluble fiber have different effects, and that the analytical measure of soluble fiber may not be adequately predictive of its physiological effects. Thus, FDA concluded that:

> Overall, the available data are not sufficient to demonstrate that it is the total soluble dietary fiber, or a specific measurable and quantifiable subcomponent, that is related to lower blood cholesterol levels. (56 FR 60582 at 60592).

The newer evidence available since the proposed rule and reviewed above do not change the conclusions reached by the earlier review. If, however, additional information becomes available to demonstrate that a specific soluble fiber-containing product, a soluble fiber-containing ingredient, or a more highly specified form of foods soluble fiber is effective in lowering bloood LDL-cholesterol and does not adversely affect other risk factors for cardiovascular disease (e.g., blood HDL-cholesterol levels), then FDA encourages manufacturers to petition for a health claim for their particular product. The same science will be applicable, regardless of whether the petition is for a single supplement-type product, a clearly specific ingredient, or a specific type of soluble fiber contained in foods.

III. Comments

A. Food Claims Versus Nutrient Claims

1. In the proposal on general requirements for health claims (56 FR 60537), FDA specifically requested comments on issues relating to health claims on the label or labeling of foods which targeted foods rather than nutrients, criteria to identify foods eligible for such claims, and possible measures to assure that consumers are not misled as to the benefit of consuming specific products.

A variety of comments submitted in response to the proposed rule on dietary fiber/CVD supported claims on foods. Specifically, relative to a claim for dietary fiber and heart disease, a few comments stated that FDA does have the authority to regulate claims about foods as well as nutrients and that the agency should allow a generic health claim on fruits, vegetables, whole grain and similar types of foods, stating that generous intakes of such foods in diets may help lower the risk of heart disease and certain forms of cancer. Other comments stated that, at this time, a scientific basis does not exist on which to authorize a specific claim for dietary fiber and heart disease, and that a food claim was more appropriate. Other comments suggested that such claims be developed in concurrence with "The Surgeon General's Report on Nutrition and Health," (Surgeon General's Report) (Ref. 63) and objectives identified in "Healthy People 200: National Health Promotion and Disease Prevention Objectives," (Healthy People 2000) (Ref. 64), and should focus on the total diet.

A number of comments stated that the amount of fat in the American diet should be lowered and the amount of dietary fiber increased through a variety of food choices from among all the food groups. Several comments favored a limited claim at point of purchase for foods that would help increase dietary fiber intake and lower fat intake. A number of comments noted that an appropriate health statement on food labels should emphasize that eating a variety of food sources of dietary fiber daily (cereals, grains, fruits, and vegetables) can decrease the risk of certain forms of cancer and heart disease. A number of comments stated that food claims, if allowed, should not give the impression that a single

nutrient (for example, dietary fiber) is responsible for the reduction in risk of heart disease. Several comments suggested that a health claim regarding dietary fiber and heart disease be made only on fruits, vegetables (fresh or processed), or whole grains and not on products that combine these foods with other ingredients (such as bread products or sauce). Other comments favored use of claims on foods but not supplements.

One comment stated that FDA should allow a fiber health claim because virtually all dietary guidelines for Americans have encouraged consumption of fiber-rich foods, including whole grain cereals, fruits, and vegetables, and that comprehensive government and other reviews by recognized scientific bodies concluded that dietary patterns that include fiber-rich foods are associated with reduced risk of colorectal cancer, heart disease, and other chronic diseases.

As the agency has discussed, in the final rule on general requirements for health claims published elsewhere in this issue of the **Federal Register**, statements about good nutrition that do not, expressly or by implication, refer to a substance are considered dietary guidance and not health claims. In this rule, the agency has concluded that the scientific evidence is sufficient to support a health claim that refers to a substance contained in certain fruits, vegetables, and grain products and relates those foods to a reduced risk of heart disease. Specific reference to the fact that these foods contain soluble fiber is authorized, since this nutrient serves as a useful marker for the broad product categories of foods which correlate with reduction in blood LDL-cholesterol levels, and consequently, with reduced risk of heart disease. Thus, the agency has been persuaded by the comments that the totality of the evidence supports a health claim which identifies foods whose use is protective against heart disease and whose selection can be facilitated by reference to the marker nutrient, soluble fiber. Because soluble fiber is usually considered a useful adjunct to, but not a replacement for, a diet low in saturated fat and cholesterol (Ref. 66), the agency is also requiring this information in the label claim.

B. General Comments

2. Several comments supported a health claim for dietary fiber and heart disease, stating that there is sufficient scientific evidence to support such a claim or that a claim is warranted because heart disease and, hence, CVD are major public health problems. Other comments stated that because such a claim would help Americans become aware of the importance of fiber, and because it is well known that population groups who consume high fiber diets have a low incidence of heart disease, these claims should be allowed. Several comments stated that FDA should consider the rapid pace of advances in knowledge that link nutritional substances to good health and disease prevention. Other comments stated that a claim regarding dietary fiber and CVD should not be allowed because overall health depends on a number of factors, such as exercise and lifestyle characteristics.

FDA agrees that CVD and, consequently, CHD are significant public health problems. The agency, in the proposal, tentatively concluded that diets high in fiber-rich foods, including whole grains, fruits and vegetables, are associated with reduced risk of CHD, and thus CVD. In the proposal, the agency also noted that these diets differ in levels of many nutrients, such as saturated fat and vegetable protein, and in types of dietary fiber, making it difficult to ascribe, from observational studies on whole diets, the observed nutrient and disease relationship to a single dietary component (56 FR 60582 at 60592 and 60593).

Several new studies that became available after publication of the proposal were suggestive of positive effects of soluble fiber intakes on blood total- and LDL-cholesterol levels, risk factors for heart disease. However, FDA has also concluded, as noted in the proposal, that the effectiveness of these fibers may be affected by other dietary components (e.g., the level of saturated fat and cholesterol in the diets), as well as by physical characteristics (e.g., particle size or water-holding capacity), or by the fiber source itself. Thus, while the agency has concluded that not all soluble fibers, i.e., as identified by the AOAC method for soluble fiber determination, are effective in lowering cholesterol, and other components of fiber-rich foods, i.e., vegetable proteins or lipids, may contribute to the cholesterol-lowering effect observed. In addition, the hypocholesterolemic effectiveness of some soluble fibers has been reported in studies in which the source of soluble fiber was consumed as an adjunct to a low saturated fat, low cholesterol, and low total fat diet.

3. Several comments stated that FDA is not following the congressional mandate to consider whether there is significant scientific agreement supporting specific health claims. Specifically, the comments argued that the agency should have placed its inquiry in the proper context by first identifying the range of specific health claims that could be made about dietary fiber and CVD, and then examining the scientific support for each claim.

FDA disagrees with this comment. The 1990 amendments did not require the agency to identify the wide range of health claims that might be made with respect to the 10 topics identified in the act and then to evaluate all published studies relevant to the claims. Rather, the 1990 amendments instructed the agency to determine whether claims respecting the 10 areas, including "dietary fiber and cardiovascular disease" meet the requirements of section 403(r)(3) or (r)(5)(D) of the act. The agency interpreted this directive in a straightforward and logical way. Indeed, FDA's chosen approach was necessary if the agency hoped to accomplish the congressional mandate within the required timeframe. Thus, FDA, in its proposed rule (56 FR 60582), focused its review of the science on those aspects of the dietary fiber and CVD relationship for which the strongest scientific evidence exists: Soluble fiber and CHD.

4. Some comments stated that FDA's denial of a health claim for dietary fiber and CVD, because of rigid application of a scientific standard higher than that mandated by the 1990 amendments, would have unfortunate public health consequences.

FDA disagrees with the comment that the agency is applying a standard higher than that mandated by the 1990 amendments. To ensure the validity of health claims, Congress enacted a scientific standard in section 403(r)(3)(B)(i) of the act. FDA intends to authorize any claim shown to meet that standard; specifically, any claim for which, based on the totality of the publicly available scientific evidence, there is significant scientific agreement, among experts qualified by training and experience to evaluate such claims, that the claim is supported by the evidence. FDA also disagrees that applying the scientific standard mandated in section 403(r)(3)(B)(i) of the act will have unfortunate public health consequences. FDA believes that for health claims to be truly educational and provide public health benefits, they must be scientifically valid and not misleading. The issue of the scientific standard is discussed in more detail in the final rule on general requirements for health claims, published elsewhere in this issue of the **Federal Register**.

5. Some comments stated that FDA used disparate criteria in assessing the relationship between lipids and CVD

and dietary fiber and CVD, but did not elaborate on this issue.

FDA disagrees with these comments. In reviewing the scientific literature for the development of its proposed rules for health claims, FDA followed the standard mandated by the 1990 amendments.

Federal Government reports and other authoritative documents have consistently concluded that there is a strong relationship between the total amount and types of dietary fat and other lipids in the diet and the risk of heart disease. In developing the proposed rule on lipids and CVD, the agency found that new evidence supported these conclusions. The weight of the evidence showed that diets low in saturated fat and cholesterol are associated with reduced blood total- and LDL-cholesterol and a lower risk of CHD.

In contrast, Federal Government reports and other authoritative documents did not reach similar conclusions that the scientific evidence supported a claim that dietary fiber per se is associated with the reduced risks of CVD. The available evidence showed an association between consumption of diets high in fruits, vegetables, and grain products—diets which are generally high in fiber—and risk of heart disease. For example, in its recommendations in the NAS report "Diet and Health" (Ref. 48), the committee on Diet and Health "agree[d] with most other expert groups in proposing that the intake of vegetables, fruits, and other sources of complex carbohydrates should be increased and that the intake of sugars should be limited." The committee further noted that "the strength of the evidence does not justify making specific recommendations pertaining to dietary fiber at this time. The committee's recommendation to emphasize the consumption of vegetables, fruits, and other sources of complex carbohydrates would, however, indirectly result in increased consumption of dietary fiber."

In developing its proposed rule on dietary fiber and CVD, the agency found that the evidence available at the time the proposal was developed did not alter these conclusions. The agency found that the scientific evidence was not sufficiently conclusive or specific for dietary fiber per se versus other components in the diet to justify use of a health claim relating intake of dietary fiber to reduced risk of CVD.

6. One comment stated that FDA failed to comply with the 1990 amendments (section 403(r)(4)(C) of the act) in that it has rejected the conclusion of authoritative Federal Government reports without justifying its decision to do so as the act requires. The comment stated that the National Cholesterol Education Program (NCEP) has concluded that soluble fiber may help reduce blood cholesterol levels. The comment refers to the NCEP 1989 consumer pamphlet (Ref. 5), which recommends breads, pasta, rice, cereals, dried peas and beans, fruits, and vegetables as good sources of complex carbohydrates (starch and fiber). The comment quotes from the pamphlet that these foods are "excellent substitutes for foods that are high in saturated fat and cholesterol. The type of fiber found in foods such as oat and barley bran, some fruits like apples and oranges, and in some dried beans may even help reduce blood cholesterol levels" (Ref. 5). The comment also noted that the NCEP expert panel report, "Population Strategies for Blood Cholesterol Reduction" (Ref. 66), supports the recommendation to consume vegetables, fruits, breads, legumes, and whole grain cereals. The comment quotes the NCEP report that "Dietary fiber supplements are not a panacea for blood cholesterol problems. Foods rich in soluble dietary fiber are, however, a useful addition to a low saturated fatty acid, low fat, and low cholesterol eating patterns* * *" and:

"Oat bran exhibits hypocholesterolemic properties due to its appreciable content of oat gum. Soluble fibers such as pectin, guar gum, locust bean gum, or psyllium in large quantity supplementation have been shown to lower total and LDL-cholesterol levels. The absolute effect on LDL-cholesterol concentrations is modest even when the amount of soluble fiber such as oat bran is consumed in appreciable amounts (60 g). This effect, however, represents a useful adjunct to an eating pattern low in saturated fatty acids and cholesterol" (Ref. 65).

FDA disagrees that, in developing its proposed rule regarding fiber and CVD, it rejected conclusions of Federal Government reports. Comments, through repetition of those portions of the text that accompanies dietary recommendations and that includes the words "soluble fiber," are attributing greater significance to the statements relating soluble fiber to heart disease risk than was given to these results by the expert panels. This selected emphasis distorts the meaning of the authoritative reports in question by failing to acknowledge important contributions to reduced risk of disease by the wide variety of nutrients and nonnutritive substances present in diets high in fruits, vegetables, and grain products. Such an emphasis also focuses attention away from changes in overall dietary patterns and their potential contributions to reducing risk of chronic diseases.

In the NCEP report (Ref. 65) cited by the comment, the expert panel noted the hypocholesterolemic effects of some soluble fibers, but recommends "a habitual pattern of eating that is consistently low in saturated fatty acids, total fat, and cholesterol." NCEP further recommended that "all healthy Americans recognize that no single food or supplement is the answer to achieving a desirable blood cholesterol level" (Ref. 65). NCEP's recommendation to Americans is to "eat a greater quantity and variety of fruits, vegetables, breads, cereals, and legumes" (Ref. 65). These food choices "will help to meet nutritional needs for minerals, vitamins, dietary fiber (including soluble fiber), and complex carbohydrates, and to replace calories from fat." Thus, the NCEP acknowledges the importance of a dietary pattern that focuses on reducing fats in the diet in order to reduce serum cholesterol. It did not attribute a protective effect from CVD to dietary fiber alone.

Neither the Surgeon General's report on "Nutrition and Health" (Ref. 63), the National Academy of Sciences (NAS) "Diet and Health: Implications for Reducing Chrinic Disease Risk"(Diet and Health) (Ref. 48), nor (The Department of Health and Human Services (DHHS)) "Healthy People 2000" (Ref. 64) found the scientific evidence strong enough to attribute the protective effects against CVD of dietary patterns high in fruits, vegetables, and grain products exclusively to the soluble fiber content of such diets. Specifically, the Surgeon General's report on "Nutrition and Health" (Ref. 63) recommends increased consumption of whole grain foods and cereal products, vegetables (including dried beans and peas) and fruits. The report states that:

"the association shown in epidemiologic and animal studies between diets high in complex carbohydrates and reduced risk for CHD and diabetes mellitus is, however, difficult to interpret. The fact that such diets tend also to be lower in energy and fats, especially saturated fats and cholesterol, clearly contributes to this difficulty. Some evidence from clinical studies also suggest that water-soluble fibers from foods such as oat bran, beans, and certain fruits are associated with lower blood glucose and blood lipid levels" (Ref. 63).

The section concludes with the statement, "Current evidence suggests the prudence of increasing consumption of whole grain foods and cereals, vegetables (including dried beans and peas), and fruits" (Ref. 63).

Similarly, the Executive Summary of the National Research Council's "Diet

and Health" recommends, "Every day eat five or more servings of a combination of vegetables and fruits, especially green and yellow vegetables, and citrus fruits. Also, increase intake of starches and other complex carbohydrates by eating six or more daily servings of a combination of breads, cereals, and legumes" (Ref. 48). The summary continues "Studies in various parts of the world indicate that people who habitually consume a diet high in plant foods have low risks of atherosclerotic CVD's, probably largely because such diets are usually low in animal fat and cholesterol. Some constituents of plant foods, e.g., soluble fiber and vegetable protein, may also contribute—to a lesser extent—to the lower risk of atherosclerotic cardiovascular diseases." The Committee does not recommend the use of fiber supplements.

"Healthy People 2000" states that recommendations from the National Cancer Institute, the Surgeon General's report on "Nutrition and Health," NAS' "Diet and Health," and "Dietary Guidelines for Americans" support increased consumption of vegetables, fruits, and whole-grain breads and cereals (Ref. 64). "Healthy People 2000" also states that further research is needed to clarify whether the effect on blood lipids is an independent effect, and if so, to quantify the relationship (Ref. 64).

Therefore, in its proposed decision not to authorize the use on the label or labeling of foods of health claims relating intake of dietary fiber to decreased risk of CVD, the agency's tentative conclusion was consistent with those of Federal Government and other authoritative reports.

FDA's position was also consistent with recommendations in the Institute of Medicine's report "Nutrition Labeling: Issues and Directions for the 1990s" (Ref. 81). In this report, the authors note that:

"there has been a great deal of interest in the specific effects of dietary fiber on several chronic diseases. The strongest argument for an increase in consumption of dietary fiber is the important contribution it makes to normal bowel function. Clear scientific associations of fiber intake with the incidence of heart disease, certain types of cancer, and diabetes mellitus have not been made. One reason may be the difficulty in designing appropriate experiments to specifically test for the effect of dietary fiber. Foods high in dietary fiber are also generally low in calories and total and saturated fatty acids and devoid of cholesterol; thus, determination of a specific fiber effect in a feeding study is difficult. Moreover, foods have a variety of fiber components and each may have different actions. Chemically and physiologically, cellulose, lignin, hemicellulose, pectin and alginate (all relatively purified fiber types) behave differently. Wheat bran, oat bran, and rice bran (all heterogeneous mixtures of fibers) are not similar in composition. It is also very difficult to analyze dietary fiber chemically, and thus it is hard to correlate the role of specific fiber components to health effects * * *" (Ref. 81).

The Institute of Medicine's report (Ref. 81) also provided specific recommendations, including: (1) "FDA and USDA should require the disclosure of fiber content per serving in grams on the nutrition information panel under the term total dietary fiber"; and (2) "FDA and USDA should discourage labeling of soluble or insoluble fiber contents until methodologies approved by the agencies allow for the adequate and reproducible quantification of the soluble and insoluble fiber contents of a variety of foods" (Ref. 81).

Therefore, FDA is not rejecting the conclusions of these government reports. In its final rule, § 101.76, the agency is permitting a claim relating dietary consumption of fruits, vegetables, and grain products, i.e., good sources of fiber, with reduced risk of heart disease.

7. One comment criticized FDA for misinterpreting the conclusions of the Government of Canada's 1985 "Report of the Expert Advisory Committee on Dietary Fiber" to the Department of Health and Welfare (Ref. 46). The comment stated that the committee expressly advocated health claims for soluble fiber and CHD.

FDA agrees that the Canadian report in question noted hypocholesterolemic effects of some soluble fiber sources, but FDA disagrees that the Department of Health and Welfare supports health claims on soluble fiber in Canada. In its comments to FDA regarding the proposed rule, dietary fiber and CVD, the Canadian Department of Health and Welfare stated its opposition to health messages. Its comment stated that health messages and claims for heart disease and cancer, among other diseases, are not permitted under the Canadian Food and Drugs Act. These diseases are considered to require medical diagnosis and treatment under medical supervision, and thus products bearing messages about them are regulated as drugs. The 1985 report suggested that, if a company desired to use a health claim, then that company should present the evidence of the product's effectiveness based on acceptable test protocols (Ref. 46).

8. One comment stated that FDA failed to note, in the proposed rule, epidemiological studies cited in the NAS' "Diet and Health" that found an inverse association between dietary fiber and CHD, even after adjusting for the possible confounding effects of calories and fat (Ref. 48).

FDA disagrees with this comment. One study was cited in "Diet and Health" that showed a protective effect of dietary fiber from cereals on risk of CHD independent of caloric intake. Results of a study by Khaw and Barrett-Connor (Ref. 31) (reviewed by FDA in the proposal) found an inverse association between fiber intake and ischemic heart disease mortality independent of calories among other dietary components. However, "Diet and Health" also states that the authors used 24-hour dietary recall to assess intake, a method which has limited applicability in the assessment of the usual dietary intake of individuals in the United States (Ref. 48). Results from the 1982 epidemiological study by Burr (Ref. 82), also cited in "Diet and Health," showed a lower risk of CHD in 10,943 vegetarians than in nonvegetarians, but their decreased risk could not be accounted for by increased fiber consumption, because many other components of the diet also differed between these two groups. Therefore, FDA did not misinterpret the conclusions of "Diet and Health" that there is no conclusive evidence that it is dietary fiber, rather than other components of fiber-rich foods, that reduces risk of CVD.

9. One comment disagreed with the indication in the proposed rule that a "risk/benefit" argument was not a sufficient or appropriate basis on which to authorize a health claim for food labels. The comment stated that, although the data for dietary fiber do not support the hypothesis for reduced risk of CVD, the "potential benefits far outweigh the potential disadvantages."

FDA disagrees with this comment. Congress enacted a scientific standard for health claims in section 403(r)(3)(B)(i) of the act. Claims must meet the statutory requirements; that is, based on the totality of the scientific evidence, there must be significant scientific agreement, among experts qualified by training and experience to evaluate such claims, that the claim is supported by such evidence. The concept of "potential benefits outweighing potential disadvantages" is not an acceptable substitute for the scientific standard mandated by Congress.

C. Specificity of the Relationship Between Soluble Dietary Fiber and Heart Disease

10. Several comments stated that FDA's refusal to authorize a health claim on dietary fiber and CVD is based

on the agency's determination to treat all dietary fiber as a group, rather than considering each fiber source individually. The comment stated that dietary fiber is composed of a diverse group of materials, as the agency observed, and each has its own physiological effects. The comment noted that certain water soluble fibers have been documented to reduce serum cholesterol, thereby lowering the risk of CHD.

FDA disagrees with this comment. In the proposed rule (56 FR 60582), FDA limited its review of the science to those aspects of the dietary fiber and CVD relationship for which the strongest scientific evidence exists: soluble dietary fiber and CHD. FDA also noted, however, that soluble fiber was a heterogenous family of fibers which vary in both chemical and physical characteristics. After reviewing the totality of the evidence, the agency is persuaded that even if soluble fiber alone is effective in reducing risk of heart disease, greater specificity than that identified by existing analytical methods is needed in order to predict the effectiveness of soluble fiber in foods.

11. LSRO submitted its document, "Dietary Fiber and Cardiovascular Disease" (Ref. 40), as a comment. In this final report, LSRO stated that it remains to be determined whether the observed effects of dietary fiber on serum cholesterol reduction result strictly from the fiber or from other components of the fiber-rich food or from a combination of these factors. The report stated that studies suggest that soluble fiber, a specific type of dietary fiber, is hypocholesterolemic, while insoluble fiber is not. Further, when foods are used, foods rich in β-glucans seem to have a more hypocholesterolemic effect. The report states that there is no indication of optimum level or even a dose-related effect, and notes that there are suggestions as to optimum level of intake for "better health" (e.g., normal bowel function) but not for prevention of disease. In addition, there are no data relating to transience of fiber effects, although this is amenable to experimental testing. The LSRO report also noted that generalization to the U.S. population is difficult. Presumably, persons at high risk, such as those with a family history of hyperlipidemia or heart disease, would benefit most.

The LSRO report also states that it is unclear whether the lipid-lowering effects observed in some studies are the result of the fact that most high fiber diets are low in fat. According to the report, most of the available evidence suggests that isolated polysaccharides, such as pectin, guar gum, locust bean gum, oat gum, and psyllium mucilloid, have the ability to lower serum cholesterol levels; however, there are no data to indicate that a fiber present in a food is the same as when it has been extracted and purified. The data suggest that diets high in fiber-rich foods can influence lipidemia, but this effect is probably due to overall changes in the diet caused by the addition of fiber sources rather than simply to a direct effect of fiber.

One comment stated that FDA failed to cite LSRO's (Ref. 39) conclusions regarding hypocholesterolemic effects of some soluble fibers.

FDA agrees that the results of clinical studies suggest that soluble fiber is hypocholesterolemic, while insoluble fiber is not. FDA also agrees that the effect of fiber-rich foods on serum lipids is related to the total diet, i.e., one that is low in saturated fat and cholesterol and high in soluble fiber-rich foods, such as vegetables, fruits, and grain products.

FDA disagrees that the agency failed to consider the conclusions of this report. Both of LSRO's reports (Refs. 39 and 40) concluded that soluble fibers were related to reduced blood cholesterol levels, but the LSRO report (Ref. 40) also concluded, as noted above, that it remains to be determined whether the observed effects of dietary fiber on serum cholesterol reduction result strictly from the fiber or from other components of fiber-rich foods or from a combination of these factors. Data available since LSRO's report (Ref. 40) provided some additional information as to the effect of soluble fiber on blood cholesterol reduction.

12. One comment stated that FDA failed to note part of the World Health Organization's (WHO) report (Ref. 71) on the relationship between soluble fiber and blood cholesterol levels (and hence CHD). The comment quotes the report, "[o]ther dietary components, such as dietary fibre, have an effect on serum cholesterol in experimental studies and are correlated in intercountry comparisons. As with fatty acids, the different forms of dietary fibre may have different effects on serum cholesterol" (Ref. 71). The comment concludes that, although the WHO report did not analyze the relevant science, it acknowledges the evidence that soluble fibers have hypocholesterolemic effects.

FDA disagrees with the comment that it failed to note the WHO statements regarding soluble fiber. Although the WHO report states that "different forms of dietary fiber may have different effects on serum cholesterol," it does not identify which form of dietary fiber affects serum cholesterol; the term "soluble fiber" was not used in the report (Ref. 71).

13. Several national health organizations with expertise in heart disease agreed with FDA's proposed conclusion, that, at this time, there is insufficient evidence to link dietary fiber, per se, to CVD. The comments stated that the proposal is consistent with the conclusions of all previous expert groups. The comments stated that the association between fiber and blood lipids is specific to soluble fiber and that specificity to fiber class is unresolved. The amount of soluble fiber necessary to produce blood cholesterol lowering is unclear; nor is it known whether (and if so, how much) the response differs by type of soluble fiber (i.e., β-glucan versus pectin). Furthermore, the comments state that FDA's review of the scientific literature (56 FR 60574) mentions the tumor-enhancing effect of soluble fibers in animal studies. They recommended that FDA not allow health claims that link fiber to risk of CVD's. The comments stated that there are insufficient data to warrant such a claim and that it is misleading to permit a claim that singles out a particular food or foods in diets. The comments stated that if there were sufficient data to make a claim, it should be stated in the context of a low fat, low cholesterol diet. It would also be necessary to specify the type of fiber, e.g., soluble fiber, in the case of CVD.

FDA agrees that a health claim for a dietary component should be stated in the context of the total daily diet and, in this case, should be specific to the type of dietary fiber. The agency has been persuaded, based on its review of the comments and its review of the scientific literature, that questions remains as to whether the cholesterol-lowering effect observed with some soluble-fiber food sources (e.g., oats) is due to the soluble fiber component or to a combination of other components associated with these foods.

14. One comment questioned the motivation behind the agency's tentative rejection of health claims for fiber and CVD. The comment stated that FDA does not want any health claims on dietary supplements and that the agency should not preclude claims because of concern that dietary supplement manufacturers will then be able to make such claims. Comments from supplement manufacturers stated that, if health claims are permitted on fiber-containing foods, then fiber supplements should also be permitted to carry a claim because there is no difference between fiber in foods and

fiber in supplements and all fiber supplements are safe. Other comments stated that FDA should authorize health claims on supplements because supplements offer an alternative to consumers who might otherwise not eat sufficient amounts of fiber in their diets.

FDA disagrees with the comment that it does not want health claims on fiber supplements and with the suggestion that it rejected dietary fiber and CVD health claims because of concern that supplement manufacturers would then be allowed to make such claims. FDA has applied the law equally to supplements and conventional foods.

As the agency's proposed rule stated, FDA proposed to deny a health claim for dietary fiber and CVD because the agency tentatively concluded that the available scientific evidence was not sufficiently conclusive or specific for dietary fiber per se. FDA notes that the comment claimed that there is no difference between fiber in foods and fiber in supplements but submitted no data were submitted to support this statement. Indeed, several expert reports (Refs. 39, 40, and 46) concluded that there is no evidence that fiber, when isolated and/or processed in foods, has the same physiological effects on serum cholesterol as consumption of the native fiber from fiber-rich foods. These reports note that the predictive capability of analytically determined values for soluble fiber and physiologic activity has not been established, and effectiveness may vary by source of fiber or by physical characteristics not detected with chemical methods of analysis (e.g., particle size or water-holding capacity). They also note that safety may vary between native and isolated sources of fiber.

D. Comments Regarding a Relationship Between Specific Soluble Dietary Fibers and CVD

15. One comment submitted a review of available literature for particular fibers. The comment stated that several of these fibers are "effective as cholesterol lowering agents and in addition, they are safe to use provided a few reasonable precautions are taken." The comment identified fibers such as locust bean gum, guar gum, oats, pectin, and psyllium mucilage as materials with hypocholesterolemic effects. Less well-tested fibers that have some hypocholesterolemic effects (for example, barley, acacia gum, dried beans, and karaya gum) were also mentioned. The comment stated that wheat fiber requires more study to determine its effects. The comment notes that, since dietary fiber represents a diverse group of materials, FDA should consider allowing health claims and statements on individual dietary fiber materials. The comment also recommended separate health claims on fibers with "hypocholesterolemic" activity, because each of these fiber materials also has a different dose-response. The comment provided some criteria on which to base the individual fiber claims.

FDA agrees that the scientific literature shows that dietary fiber is a complex group of dietary substances with differing chemical, physical, and physiological properties, and that not all soluble fibers are alike in their hypocholesterolemic properties. FDA disagrees with the recommendation to allow individual health claims on various soluble fibers, but does concur that the effectiveness of individual fibers in foods may be documented for specific food products or for fibers whose physical and chemical characteristics are well specified (e.g., oat brans meeting specified parameters). Thus, if manufacturers can document, through appropriate studies, that the soluble fiber in their particular food is effective in lowering LDL-cholesterol, and has no adverse effects on other heart disease risk factors (e.g., HDL-cholesterol), then FDA encourages manufacturers to petition for a health claim for their particular product or ingredient. Additionally, if new evidence becomes available which more clearly identifies what type of soluble fiber is effective, this also would be appropriate for a petition.

16. Another comment stated that part of FDA's difficulty in interpreting data on dietary fiber and CVD results from the consideration of soluble fiber as a single nutrient instead of as a class of diverse substances. The comment stated that data exist to support at least one soluble fiber, β-glucan, as the substance responsible for the majority of the cholesterol-lowering effects observed with some fiber sources. Another comment stated that there is a preponderance of literature supporting oat bran and its hypocholesterolemic effects and that the active mechanism behind oat bran's effectiveness is the β-glucan component. The comment suggested that the agency allow foods to be identified that contribute to eating patterns that reduce the risk of disease.

FDA agrees, as discussed in the proposal, that dietary fiber is a diverse group of substances and not all soluble fibers are alike in their hypocholesterolemic properties. FDA also agrees, based on new data submitted as comments, that there is evidence to suggest that β-glucan has hypocholesterolemic properties. However, as noted in the meta-analysis (Ref. 125), other components of oats, such as tocotrienols and oat oil, may play a role in the reduction of blood LDL-cholesterol levels. However, FDA is authorizing a claim on fruits, vegetables, and grain products—foods that are good sources of soluble fiber and other substances that may have cholesterol-lowering properties.

17. Comments from a health professional organization stated that several studies have shown that soluble fibers, such as those in oat, beans, psyllium, and guar, appeared to lower serum cholesterol, at least when given in large amounts. The comment further stated that weight loss observed in some studies may possibly be far more important than fiber in contributing to cholesterol reduction.

FDA agrees that weight loss associated with test diets may affect the ability to differentiate between the effects of the test substance (i.e., soluble fiber) versus the well-documented effect of weight loss on blood total- and LDL-cholesterol. This was discussed in the meta-analysis submitted as a comment (Ref. 125). Several studies observed reductions in blood cholesterol levels in studies in which loss did not occur. For example, in a study by Marlett et al. (Ref. 124), submitted with another comment, there was no significant weight loss in either the control or soluble fiber (oat bran) groups during the fiber intervention period. Serum cholesterol was significantly lower in the oat bran group than in the control group. Spiller et al. (Ref. 87) reported no weight changes in two groups receiving either guar gum or oat fiber. Both groups experienced significantly lowered serum cholesterol. In two other studies (Refs. 118 and 120), there was no significant difference in the weight loss between subjects consuming oat bran (Ref. 120) or psyllium cereal (Ref. 118) and those consuming wheat bran. The oat bran group had significantly lower serum cholesterol than the wheat group and compared to the control period. Thus, while the agency agrees that weight loss may be a confounding factor, the new evidence is consistent with the concept that consumption of diets high in certain soluble fiber-rich foods, independent of body weight, has a beneficial effect on blood cholesterol levels.

E. Comments Regarding FDA's Interpretation of Specific Studies

Some comments cited references that were already reviewed by FDA or the consensus documents, or were studies of questionable relevance to human CVD (e.g., studies evaluating

postprandial glucose response of fiber diets). Some abstracts were also cited that do not provide sufficient information for evaluation. Review articles that provided no new data were also included with some comments.

18. One comment stated that the study by Kahn et al. (Ref. 25) showed significant decreases in relevant parameters in the test groups versus baseline and that the authors concluded that soluble fiber "appears to be quite effective" in lowering those parameters. In the proposed rule, FDA reported that there was no significant difference in serum cholesterol between the test group and the control group.

FDA notes that it did report that a significant difference in serum cholesterol existed between baseline and intervention values if the results are examined without consideration of the immediate versus delay constraint of the design. The agency initially concluded that the study did not support an effect of oat bran on serum cholesterol lowering because of the lack of statistical significance when examining only the difference between the immediate intervention group and its control. FDA believes that the study design should have been modified to overcome this problem of the time delay in comparing the groups. However, after further review, FDA agrees with the authors (Ref. 25) that, after correcting for the time delay, the study does show that oat bran supplementation reduced serum cholesterol.

19. One comment criticized FDA for calling a "p value" of 0.052 in the paper by Anderson et al. (Ref. 5) "nearly significant." The comment suggested that a more precise term would be "borderline significant."

FDA acknowledges that the term "borderline significant" is more commonly used professionally, but considers that this does not negate the need for caution in reviewing the results of this paper.

20. One comment stated that FDA failed to report the modest effect, from a study by Bell et al. (Ref. 12), of a pectin-enriched cereal on serum cholesterol.

FDA disagrees with this comment. Of the two fiber-enriched cereals (one enriched with psyllium and the other with pectin) tested by Bell et al. (Ref. 12), FDA reported that only psyllium demonstrated a significant reduction in cholesterol. The agency correctly stated that the psyllium-enriched diet demonstrated significant lowering of total- and LDL-cholesterol, but that the pectin did not.

21. A comment disagreed with FDA's statement that the study by Davidson et al. (Ref. 15) did not demonstrate significant reductions from baseline levels in total cholesterol with daily intakes of up to 2 oz of oatmeal (1.2 to 2.4 g β-glucan/day) or 1 oz oat bran (2.0 g β-glucan/day) in persons on a Step 1 diet.

FDA correctly reported that only the higher fiber intake groups showed statistically significant effects. The small sample size may have prevented seeing an effect in the lower doses. FDA agrees that, based on the results of this study, an intake of soluble fiber (in this case, β-glucan from oats) of about 3 g per day or more was beneficial in that it resulted in a significant lowering of serum cholesterol in persons consuming a low-fat diet.

22. A comment asked FDA to consider a result from a study by Newman et al. (Ref. 50) which used β-glucan from barley and compared it to wheat fiber. The cholesterol levels of the high β-glucan group did not differ significantly from baseline after four weeks. The author explains this lack of significance by citing the small sample size and small amounts of β-glucan consumed.

FDA does not necessarily disagree with this comment, but considers that it was correct in not assessing the results as positive (i.e., a true difference exists) because a statistically significant effect was not demonstrated.

23. One comment stated that FDA failed to consider significant the results by Van Horn et al. (Ref. 68). In this study, the investigators tested the effects of oat-bran intervention on serum cholesterol levels in subjects with normal or mildly elevated serum cholesterol levels. The authors reported a difference ($p = 0.074$) in serum cholesterol between the oat group and the control after 8 weeks.

FDA did not consider this result significant because the small sample size was not a problem in this study and the p values reported are one-tailed. Such values allow leeway over the more conventional and conservative two-tailed tests.

24. One comment stated that FDA did not properly interpret the results of a study by McIntosh et al. (Ref. 44), which compared the cholesterol-lowering effect of β-glucan from barley to that of wheat fiber.

FDA disagrees with this comment. Although there was a significant difference between cholesterol levels of the two groups, this was largely due to a rise in total cholesterol that occurred in the wheat group compared to baseline. In this case, it is not possible to know whether wheat acted as a placebo, or whether wheat itself is cholesterol-raising. However, because the group fed barley did not show a significant lowering of cholesterol from their own baseline level, the agency does not find that a positive effect of barley was demonstrated.

25. Another comment addressed a study by Burr et al. (Ref. 13) that examined whether there was a change in mortality rates between men given dietary advice to increase fiber intake or to reduce fat intake. The comment was specifically concerned with FDA's conclusion that the study was not able to show a difference between mortality rates in the two groups. The comment stated that the results show that increasing fiber intake is no less effective than decreasing fat intake in the prevention of CHD.

FDA disagrees with this comment. Because there was no group in this study which acted as a control (no changes in diet), the study does not provide evidence that either diet in the studies is effective or that neither is effective. The agency finds that the study does not add to the evidence of the effects of fiber.

26. One comment stated that a study by Little et al. (Ref. 42) that shows that lowering fat is responsible for significant lowering of total cholesterol, while increasing fiber is not, did not specify the type of fiber (i.e., soluble versus insoluble) and should not be considered as part of the fiber-CHD evaluation.

FDA disagrees with this comment. The agency considered any fiber study which might be relevant to the health claim. However, the weight given to study results was influenced by several factors, including the quality and usefulness of the information on soluble fiber intakes.

27. One comment noted that the study by Demark-Wahnefried et al. (Ref. 16) showed a significant drop in total serum cholesterol in all three of the following dietary groups: A high fiber, low-fat diet; a low-fat diet alone; and a regular diet with fiber added. The comment contended that, because there was no significant difference between any of the groups, this study showed that increasing soluble fiber intake is as effective as reducing fat intake.

FDA disagrees with this comment. This study does not support a conclusion that soluble fiber is as effective as reducing fat intake. These results showed that the cholesterol-lowering effect of a low-fat diet was not further enhanced by the addition of fiber. Additionally, there was a significantly decreased consumption of fat and cholesterol in all groups; this is consistent with the hypothesis that fat displacement is one mechanism by

which high fiber diets lower total cholesterol.

28. Another comment also criticized FDA's review of the Demark-Wahnefried et al. study (Ref. 16). The comment stated that, according to the Keys equation for predicting changes in blood cholesterol levels from changes in intakes of fatty acids, only 40 percent of serum cholesterol's lowering is explained by changes in dietary fat.

FDA disagrees with this comment. The agency's evaluation of this study pointed out the lack of significant difference between cholesterol lowering on the regular diet plus oats or the low fat, low cholesterol diets. The study did not estimate how much, if any, of the remaining 60 percent is attributable to oat bran.

29. One comment stated that FDA misinterpreted the results of the study by Keenan et al. (Ref. 26) by failing to note that the control group decreased its soluble fiber intake over the study period, thus accounting for the return to baseline for serum cholesterol in this group by the end of the study.

FDA disagrees that it misinterpreted the results of this cross-over study, in which the authors compared the hypocholesterolemic effects of oat- or wheat-supplemented Step 1 diets with a control group on the Step 1 diet only. Although FDA recognizes the problem with the control group, the agency correctly reported that there was a lack of significance in the change in serum cholesterol in the oat-wheat group during the oat phase. Recognizing that the control group decreased its soluble fiber over the study period may suggest redoing the study with a better control of soluble fiber in this group.

30. Another comment also disagreed with FDA's criticism that the study by Keenan et al. (Ref. 26) did not have a placebo. The comment stated that the wheat group was considered a placebo because it has been well documented that wheat has virtually no cholesterol lowering properties. A similar comment was made regarding FDA's criticism of a study by Swain et al. (Ref. 57) in which wheat was also used as a placebo.

FDA has expressed concern about the use of wheat as a placebo due to its inconsistent effect on serum cholesterol in some reports. Although the study by Keenan demonstrated an increased total cholesterol in the "oat-wheat" group of 6 percent above baseline during the wheat period, in Swain's study the wheat group showed a 7 percent decrease in serum cholesterol. Based on these studies and other reviews, FDA now believes that these variations in serum cholesterol may be a function of the amount and method of administration of the wheat and must be reviewed with caution. Rather than discounting the use of wheat as a placebo, FDA believes that the placebo, whether it is wheat or another fiber, must be evaluated individually for each study.

31. One comment suggested that the FDA failed to note that the study by Davidson et al. (Ref. 15) was specifically designed to determine whether β-glucan has a dose-response effect on serum cholesterol after reducing and controlling for fat intake. Subjects in this study consumed a Step 1 diet with two levels of oat bran incorporated into the diet. FDA disagrees that it failed to note this point. The authors of the study stated that there is a "lack of continued dose response" (Ref. 15). In addition, the authors say that "the impact of fat substitution on serum cholesterol reduction with oat cereals cannot be completely excluded" due to the lack of isocaloric control for the higher-dose treatment groups (Ref. 15).

32. Another comment on the Davidson et al. study (Ref. 15) stated that FDA's criticism of the lack of a control group was not valid due to the 6-week wash-out period. The comment states that, during this wash-out period, the serum cholesterol values of all treatment groups returned to baseline levels, suggesting that the hypocholesterolemic effects observed were the result of oat β-glucan supplementation.

Although the wash-out period is not the equivalent to a true control, FDA agrees that, considered with the evidence from the intervention period, the decrease in serum cholesterol suggests an effect of β-glucan at the higher levels of intake.

33. One comment criticized FDA for failure to note regarding the study by Bell et al. (Ref. 11) that the psyllium group on the Step 1 diet had significant reductions in total cholesterol levels as compared to the placebo (wheat fiber) controls.

FDA disagrees with this comment. The problem with this study is that, during the second 8-week test period, the psyllium group's total cholesterol had risen to only 1.5 percent below the baseline level. The significant difference still exists between placebo and test group because the mean serum cholesterol level of the placebo group actually increased to a level higher than baseline. The agency believes that these results weaken the support for cholesterol-lowering effectiveness over time on this diet.

34. One comment stated that the study by McIvor et al. (Ref. 45), showing no effect of guar gum on serum cholesterol in a population of overweight noninsulin dependent diabetics, should not have been discussed in the proposed rule. The comment explained that this was not a typical population group (diabetics consume large amounts of fiber products to help with carbohydrate metabolism), and the objective of the study was to test the safety of guar. In addition, the comment states that the diets were uncontrolled so the results could be confounded by additional fat from the granola-type bars in which the guar gum was incorporated.

FDA disagrees with this comment. Although overweight diabetics may not be a typical group, FDA did not eliminate the noninsulin diabetics from the criteria for evaluating fiber studies; insulin-dependent diabetics are excluded, however. Although the objective of the study was not to evaluate cholesterol-lowering effects, this information was presented and FDA considered it to be relevant. In addition, adding fiber to a diet without changing the overall diet is probably a very typical form of consumer behavior. The agency also notes that it did not say that fiber intake had no effect in this study, but rather that the results are "inconclusive."

35. One comment addressed FDA's review of the study by Lo and Cole (Ref. 43), in which pooled periods only show a significant difference between the placebo and soy fiber groups. The comment stated that the placebo's effects on total cholesterol were insignificant, while soy's effects were significant.

FDA disagrees with this comment. As shown in table IV of the paper, the 2 percent decrease in serum cholesterol reported after soy fiber consumption in Group B is not significant. FDA questions the inconsistency of the results (i.e., after the placebo effect is gone, is Group B more representative of the effect?). The order of treatment effects on the results should have been considered in the conclusion.

36. One comment criticized FDA's review of the study by Superko et al. (Ref. 56), which FDA discounted as demonstrating significant differences between fiber groups. The comment stated that FDA has failed to consider the significant reductions in serum cholesterol levels between baseline and test group consuming guar gum.

FDA disagrees with this comment. While it is true that at 4 weeks there was a significant difference between total cholesterol levels from baseline, at 8 weeks the p value dropped to 0.15, which is not statistically significant. When FDA calculated the difference

between the placebo to guar supplementation at the 4 and 8 week intervals, neither was significant as defined by a p value of 0.05 or less.

37. One comment stated that FDA incorrectly reported results in the study by Beling et al. (Ref. 10). The comment stated that FDA reported nonsignificant reductions in serum cholesterol between the group using oat-enriched cereal and the control group.

FDA agrees with this comment. After reexamining the results, FDA notes that they show a significant difference between the two groups, thus adding support to a cholesterol-lowering effect of soluble fiber-rich foods in combination with consumption of a low-fat diet.

38. Another comment stated that the weight loss differences reported in the study by Beling et al. (Ref. 10) were not significant between groups, so effects of weight change should be similar. The comment also stated that it is not possible to completely "blind" a study that uses ready-to-eat cereal.

FDA agrees with the comment.

39. One comment stated that FDA criticized the lack of baseline fiber intake data in the study by Gold and Davidson (Ref. 19), but did not explain the significance of that assertion.

FDA considers baseline fiber intake data necessary to determine if the effect seen could have resulted from fat displacement in the diet.

40. One comment criticized FDA's evaluation of a study by Stewart et al. (Ref. 55) and stated that FDA failed to consider the effect after adjustment when reporting the study as nonconclusive of an effect. The study by Stewart and colleagues (Ref. 55) noted that the psyllium supplement administered had a nonsignificant effect on total serum cholesterol when dose was not considered, but a significant effect after adjusting for dose.

FDA disagrees with this comment. Referring to both Figure 1 and Table 4 in the study, the linear trend is driven by the higher dose values, which have very small numbers compared to the overall study population. In addition, the author has excluded the 739 control subjects in the dose-specific analysis for a dose of 0 (no psyllium intake), which, if included, would most likely eliminate any trend. The results of the study do not support any overall effect of psyllium on serum cholesterol.

41. One comment stated that FDA unnecessarily distinguishes studies using separate fiber supplements from those using fiber-enriched foods.

FDA disagrees with this comment. FDA is applying a consistent legal standard to its consideration of studies on fiber supplements and studies of fiber-rich foods. However, from a scientific standpoint there is reason to believe that the use of fiber at higher intakes and higher concentration (i.e., a fiber supplement taken as a single dose prior to meals) may well differ from the typical intake of fiber from foods (i.e., smaller amounts of fiber consumed throughout the day). If an effect is seen when fiber is consumed at higher intakes and higher concentrations, it cannot be assumed that there is a linear dose-response effect that will translate into significant effects at more usual levels of intake. Conversely, if an effect is seen when fiber is consumed with more typical intake from foods, it may not automatically translate into an effect from fiber supplements. Additionally, isolated fibers (as used in supplements) may vary in chemical and physical characteristics from native or less processed fibers. Since a mechanism of action for soluble fiber in reducing blood LDL-cholesterol levels has not been identified, it is possible that processing of soluble fibers may affect their ability to lower blood cholesterol levels.

F. Comments Regarding Applicability to the General Population/Public Health Aspects

42. One comment criticized FDA for including, in the dietary fiber-CVD proposal, the criterion that studies must be conducted in persons who generally represent the healthy U.S. population, i.e., adults with cholesterol readings below 300 mg/dL. The comment stated that this criterion eliminated many valid studies that demonstrate significant scientific agreement for a claim about the relationship between soluble fiber and CHD; and secondly, that these studies remain useful to demonstrate soluble fiber's hypocholesterolemic effects at lower doses, for longer durations, in conjunction with reduced-fat diets.

FDA agrees that populations at higher risk may provide a more sensitive group for identifying a nutrient/disease relationship. However, extrapolation of results from a high risk group to the general population must be done with caution and generally requires some confirmatory studies in the general population. FDA included, in its review, studies on persons considered to be at high risk, i.e., with levels of blood total cholesterol between 200 and 300 mg/dL. FDA, thus, included a large segment of the general population whose risk levels fall in this range, but excluded the much smaller segment of persons with blood total cholesterol levels above 300 mg/dL, because these people often have multiple and serious health problems, making it difficult to generalize results beyond the particular study populations. According to the National Center for Health Statistics (Ref. 79), only 5 percent of the U.S. adult population of men and women have serum cholesterol levels 300 mg/dL or higher. Results of two studies (Refs. 9 and 59) showed that subjects with a mean serum cholesterol level ≤300 mg/dL had significantly lowered serum cholesterol at the end of the test period compared to baseline. Final serum cholesterol levels, however, was still greater than 300 mg/dL. Thus these individuals remained severely hypercholesterolemic and at high risk for CVD.

It is also important to note that the hypocholesterolemic effect in these two studies (Refs. 9 and 59) and many of the other studies attenuated with time, and serum cholesterol levels increased toward baseline. Thus, the agency does not agree with the comment that such results are necessarily useful to demonstrate a long-term hypocholesterolemic effect of soluble fiber at lower doses. Interpretation of results depends on how well compliance with the test regimen was accomplished.

Of the other 33 studies reviewed in the proposed rule (56 FR at 60596 through 60609), the mean blood total cholesterol was in the mid- to upper-200's (mg/dL) because many of the subjects had individual serum cholesterol levels greater than 300 mg/dL. These studies were included in the evaluation of the relationship between dietary fiber and CVD if they met the other evaluation criteria.

43. Another comment criticized FDA for separately evaluating studies using "typical" or "usual" American diets (i.e., approximately 37 percent of calories from fat) and those using a reduced fat (Step 1) diet. The comment stated that the agency should have given equal weight to studies whether they involved a "typical" American diet or a reduced fat (Step 1) diet.

FDA disagrees with this comment. As stated in the proposed rule (56 FR 60582 at 60587), "Responses of blood cholesterol levels to dietary treatment are affected by many factors, including initial (baseline) blood cholesterol levels and dietary factors (i.e., the level of saturated fat and cholesterol in the diet)." Because serum cholesterol is responsive to dietary intakes of saturated fat and cholesterol, FDA separated the studies on the basis of whether fiber effects were being evaluated as part of a typical American diet or as part of a reduced fat diet.

Results of fiber studies become confounded when the test diet is not adequately controlled, or not assessed at all, and when subjects make their own changes to their diets by consuming less total and saturated fat. In such cases, the true effects of fiber, if any, cannot be adequately determined. Although the agency grouped studies based on type of diet, it did give them equal weight based on the evaluation criteria.

44. One comment stated that FDA failed to consider studies reporting only modest reductions in serum cholesterol as strong evidence of soluble fiber's effectiveness. The comment refers to the public health significance of even a small reduction in serum cholesterol; i.e., a 1 percent reduction in serum cholesterol levels predicts approximately a 2 percent reduction in CHD (Ref. 41).

FDA disagrees with this comment. FDA recognizes that changes in serum cholesterol in fiber-feeding studies are generally small. However, if, due to the sample size of the study, this change is not sufficient to demonstrate statistical significance beyond that which may occur by chance (generally accepted by epidemiologists and biostatisticians as $p<.05$), it cannot be concluded that a true effect has been observed.

45. Another comment stated that there is no scientifically valid basis for excluding studies involving subjects whose blood cholesterol levels exceed 300 mg/dL.

FDA disagrees with this comment. As stated above, 5 percent of the U.S. population have serum cholesterol levels greater than 300 mg/dL (Ref. 79). It is important to remember that "the magnitude of plasma lipid response is frequently related to the initial plasma lipid status of the experimental subjects. Persons with higher plasma lipids initially usually experience the greatest plasma lipid response to diet intervention" (Ref. 33). What may cause an effect to look significant may be driven largely by the magnitude of the change, which is more likely to be observed in those individuals with very high serum cholesterol levels. To base conclusions on one group that will respond to a much greater extent than another is misleading as to those persons with normal to moderately elevated serum cholesterol levels, who comprise 95 percent of the adult population.

46. One comment noted that population compliance was essential to the success of dietary intervention for improved public health and that adding fiber to the diet is more acceptable to consumers than removing fat.

FDA agrees that compliance is an important factor, but, with respect to fiber and CVD, it must first be established that addition of fiber alone to the diet is an effective means of reducing serum cholesterol.

G. Comments Regarding Issues of Study Design, Confounders, Fat, etc.

47. One comment stated that FDA criticized studies that do not control for the effects of low dietary fat when examining increased dietary fiber consumption and cholesterol reduction.

FDA disagrees with this comment. Although many studies provide compelling evidence of the effect of a combined low-fat, high fiber diet on lowering serum cholesterol, FDA examined the scientific evidence to determine whether a specific relationship existed between soluble dietary fiber and risk of heart disease, and whether sufficient scientific evidence was available to support a health claim for dietary fiber and heart disease.

48. Another comment criticized FDA's evaluation of a study by Van Horn et al. (Ref. 67) for inappropriately discounting the correlation of fiber intake with serum cholesterol by pointing out that many other nutrient intakes besides fiber showed correlations with cholesterol levels. The comment stated that dietary fiber had correlations with CHD that were as statistically significant as those for fat and CHD, and this argues for a finding that significant scientific agreement supports a claim about the relationship between fiber and CHD.

FDA disagrees with this comment. FDA again emphasizes that many other nutrient intakes in addition to dietary fiber show statistically significant correlations. In a cross-sectional survey analyzed in this manner, one of the first things that must be considered when many factors show significance is whether they are highly correlated with each other. If this is the case, displacement of fat in the diet by fiber is one explanation for the observed effect.

49. Another comment argued that, although FDA has stated there may be other micronutrients or components in vegetables, cereal, fruits and berries other than soluble fiber that may have contributed to the cholesterol-lowering effects of some soluble fiber-containing foods, the agency has failed to identify them.

FDA agrees that it did not identify other components in foods that may have serum cholesterol lowering effects. Its point in this statement was that attribution of effects to soluble fiber per se, when foods contain a wide range of vitamins, minerals, and other substances, is misleading. The authors of the meta-analysis (Ref. 125) also noted that other components of oats may play a role in the cholesterol-lowering properties observed in human studies.

50. Another comment criticized FDA's evaluation of a study by Van Horn et al. (Ref. 69).

FDA stands by its evaluation of the Van Horn study. FDA criticized the study because there are significant changes in diet between the control and test group in total fat intake, saturated fat intake, and monounsaturated fat intake, and the authors did not demonstrate that these changes did not contribute to the cholesterol-lowering effect observed.

51. Another comment suggested that weight loss is not a confounder, but rather a result of fiber's ability to effect weight reductions independently of changes in caloric or fat intake.

FDA disagrees with this comment. Although this may be a possible mechanism of action, no studies reviewed have provided clear evidence of this.

52. One comment stated that confounding variables and lack of a mechanism of action are not a valid basis for denying a link between ingestion of fiber and reduced risk of heart disease which experimental evidence shows in fact exists.

FDA disagrees with the comment's description of the basis for its proposed action. If factors such as weight loss, changes in diet, lifestyle changes, and/or exercise, which are known to influence serum cholesterol, are not controlled in a clinical study, or if analytical methods for determining the soluble fiber content in food sources are not clearly established, the specificity for an effect of soluble fiber on serum cholesterol cannot be determined. In its proposal, FDA made a tentative decision to deny a health claim regarding dietary fiber and CVD for a number of reasons, including confounding factors identified in many of the clinical studies reviewed, but not because there is no recognized mechanism(s) of action for hypolipidemic effects of different soluble fibers. For a more thorough discussion of FDA's proposal to deny a health claim on dietary fiber and CVD in the proposed rule, see 56 FR 60582 at 60591 through 60592. FDA believes that, for health claims to be educational and result in changed eating habits, the claims should be truthful and not misleading.

H. Conclusions From Comments

FDA agrees with many of the comments that a problem in determining the relationship between dietary fiber and heart disease is the fact that dietary fiber is a diverse group of chemical substances that may be associated with different physiological functions, and that the analytical methodology to identify the soluble fiber content of a food may not be predictive of the likely physiological effect.

IV. Decision to Deny a Health Claim Relating Dietary Fiber to Reduced Risk of CHD

Overall, the currently available scientific evidence is not sufficiently conclusive or specific for soluble fiber per se to justify use of a health claim relating the intake of dietary soluble fiber to a reduced risk of heart disease. A major limitation in designing and evaluating research studies has been the need for better defined measures of dietary soluble fiber and standardized descriptions for source, type, and amount of dietary soluble fiber. Commonly used analytical methodologies do not detect many of the characteristics that may vary among fibers and that may be related to biological function (e.g., particle size, chemical composition, water-holding capacity). Other components associated with soluble fiber in foods (e.g., tocotrienols) may also have some cholesterol-lowering capabilities. The inability to detect many of the differences among fibers, fiber components, and other substances in foods which contain soluble fiber, and the general lack of conclusions as to the mechanism(s) of action of soluble fibers raise questions about the ability of commonly used analytical measures of dietary fiber to adequately predict biological actions of specific fibers. For these reasons, FDA is not authorizing use of a health claim relating dietary fiber to a decreased risk of CHD.

FDA's decision is consistent with recent conclusions reached about the state of the scientific evidence by the National Heart, Lung, and Blood Institute of the National Institutes of Health (Ref. 155) and recommendations in the Institute of Medicine's report "Nutrition Labeling: Issues and Directions for the 1990s" (Ref. 81). This report notes that there has been great interest in the specific effects of dietary fiber on several chronic diseases. According to the report, the strongest argument for an increased consumption of dietary fiber is the important contribution it makes to normal bowel function. Clear scientific associations of fiber intake with the incidence of cancer, heart disease, and diabetes mellitus have not been made. The report indicates that one reason for this may be the difficulty in designing appropriate experiments to test specifically for the effect of dietary fiber. Foods high in dietary fiber are also generally low in calories and total and saturated fatty acids and devoid of cholesterol; thus, determination of a specific fiber effect in a feeding study is difficult. Moreover, according to the report, foods have a variety of fiber components and each may have different actions. Chemically and physiologically, cellulose, lignin, hemicellulose, pectin, and alginate (all relatively purified fiber types) behave differently. Wheat bran, oat bran, and rice bran (all heterogeneous mixtures of fibers) are not similar in composition. It is also very difficult to analyze dietary fiber chemically, and thus it is hard to correlate the role of specific fiber components to health effects (Refs. 48 and 81). Therefore, FDA is not authorizing the use on the labels and labeling of foods of health claims relating to an association between the ingestion of dietary fiber (particularly soluble fiber) and a reduction in the risk of heart disease. In reaching this decision, the agency considered all comments received in response to its proposed rule (56 FR 60582), and reviewed the scientific literature that became publicly available after the proposal's publication and data submitted with comments.

V. Decision to Allow a Health Claim on Foods Relating Diets Low in Saturated Fat and Cholesterol and High in Fruits, Vegetables, and Grain Products, Foods That Contain Fiber, Particularly Soluble Fiber, to a Reduced Risk of CHD

FDA has reviewed the numerous authoritative documents, including Federal government reports, as well as recent research on dietary fiber and CHD risk. In addition, the agency considered all comments received in response to its proposed rule. The agency has concluded that the publicly available scientific evidence supports an association between diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products, foods that are low in saturated fat and cholesterol and are good sources of dietary fiber, to reduced risk of heart disease.

FDA agrees with the comments that show that dietary patterns that are low in saturated fat and cholesterol and high in fruits, vegetables (including legumes), and grain products are associated with a decreased risk of CHD. Although the specific roles of the numerous potentially protective substances in such plant foods are not yet understood, populations with diets rich in these foods experience many health advantages, including lower rates of heart disease. Currently, there is not scientific agreement as to whether the observed protective effects against heart disease are due to a combination of nutrient components of the foods, including soluble fiber, to other components of soluble fiber-rich diets (for example, potassium and magnesium), to displacement of saturated fat and cholesterol from the diet, or to non-nutritive substances in these foods.

Thus, the conclusion that diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products, foods low in saturated fat and cholesterol and containing soluble fiber, are associated with a reduced risk of heart disease is consistent with the available scientific evidence. The fact that these foods contain dietary fiber, particularly soluble fiber, can serve, therefore, as a useful marker for identifying those fruits, vegetables, and grain products which, when added to diets low in saturated fat and cholesterol, may help in reducing blood LDL-cholesterol levels. As discussed in the final rule on general requirements for health claims, published elsewhere in this issue of the **Federal Register**, statements about good nutrition that do not expressly or by implication refer to a substance are considered dietary guidance and not health claims. In this rule, FDA is authorizing the inclusion of a reference to dietary fiber (a substance) in a statement about the value of fruit, vegetables, and grain products in reducing the risk of heart disease. Thus, the health claim permitted under this regulation to be used on labels and labeling of certain foods associates diets low in saturated fat and cholesterol and high in vegetables, fruit, and grain products, that contain soluble fiber with a reduced risk of heart disease.

VI. Rationale and Description of the Final Regulation

A. Relationship and Significance Statements

In new § 101.77(a), the summary of the relationship between diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain soluble fiber and reduced heart disease risk is consistent with the conclusions reached in the review of the scientific evidence. Although the specific roles of dietary soluble fiber, or

of specific soluble fibers and fiber components, and the multiple nutrients and other substances contained in these foods, are not yet fully understood, many studies have shown that diets high in soluble-fiber-containing foods are associated with lower blood LDL-cholesterol levels and with reduced risk of heart disease. These diets are generally low in saturated fat, cholesterol and total fat, nutrients known to have a detrimental effect on blood LDL-cholesterol levels, and therefore, on risk of heart disease. Dietary soluble fiber can be used as a marker to identify the types of foods which correlate with reduced heart disease risk, and whose addition to diets low in saturated fat and cholesterol is considered to be useful in lowering blood LDL-cholesterol (Ref. 66). The relationship statement in § 101.77(a) also includes other information about heart disease, such as risk factors, as in other authorized health claims.

New § 101.77(b), on the significance of the relationship between consumption of diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain soluble fiber and reduced risk of heart disease, includes the information that U.S. diets tend to be high in saturated fat and cholesterol and low in fiber-containing fruits, vegetables, and grain products. A discussion of current dietary guidelines on recommended servings of fruits, vegetables, and grain products is also provided.

B. Nature of the Claim

In new § 101.77(c)(2)(i), FDA is authorizing a health claim relating diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain soluble fiber to reduced risk of heart disease. In new § 101.77(c)(2)(i)(A), the agency is requiring, consistent with other authorized claims, that the relationship be qualified with the terms "may" or "might." These terms are used to indicate that not all persons can necessarily expect to benefit from these dietary changes.

In new § 101.77(c)(2)(i)(B), the agency, consistent with other authorized claims, is requiring that the claim use the specific terms "heart disease" or "coronary heart disease" to define the type of disease dealt with by this claim. These disease terms reflect terms commonly used in dietary guidance materials, and are also reflective of the scientific evidence which links these dietary factors to heart disease risk via the intermediate mechanism of reducing blood LDL-cholesterol levels, rather than to the broader category of cardiovascular disease.

In new § 101.76(c)(2)(i)(C), the agency is requiring that the claim discuss only those fruits, vegetables, and grain products that contain dietary fiber, rather than all fruits, vegetables, and grain products. Diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain fiber, particularly soluble fiber, are correlated with reduced heart disease risk. Thus, a claim discussing those fruits, vegetables, and grain products that contain the marker nutrient, but does not attribute a protective effect to soluble fiber, is consistent with current scientific knowledge.

New § 101.77(c)(2)(i)(D) specifies the terms that can be used to describe the fiber component of the fruits, vegetables, and grain products that bear a health claim. Consistent with the state of the scientific evidence, this paragraph permits a choice among a number of terms, but does not allow terms for specific types of fiber to be used, e.g., those connoting the origin of the fiber. The term "soluble fiber" may be used in combination with a more general term for fiber. This permits reference to soluble fiber, which is a useful marker nutrient for foods associated with reduced risk of heart disease. However, the present scientific evidence does not permit a determination of whether it is the soluble fiber or other components in these foods or displacement of fat that provides the protective effect. Given these uncertainties about the specific role of soluble fiber, it would be misleading to place undue emphasis on soluble fiber standing alone.

New § 101.77(c)(2)(i)(F) requires that health claims specify that development of heart disease depends on many factors. This requirement is intended to prevent consumers from being misled that fruits, vegetables, and grain product intake is the only factor connected with heart disease risk.

In new § 101.77(c)(2)(i)(E), FDA is prohibiting, consistent with other authorized health claims, more specific use of dietary terms than is warranted by the current state of the scientific evidence. New § 101.77(c)(2)(i)(G) is also consistent with other authorized health claims, and prohibits any attribution of degree of risk for heart disease and fiber-containing fruits, vegetables, and grains. These requirements also standardize use of terms, thus minimizing consumer confusion as they compare food labels across products, or as they compare a health claim to the nutrition information panel.

C. Nature of the Food

New § 101.77(c)(2)(ii)(A) requires that the food bearing the health claim be or contain a fruit, vegetable, or grain product. Because the claim relates to diets high in these foods, it would not make sense for it to appear on the labeling of another type of food. A health claim that appears on a food that meets all the requirements in § 101.77(c)(2)(ii), but contains only a trivial amount of fruit, vegetable, or grain product, could be considered misleading and might misbrand the food under section 403(a) of the act.

FDA, consistent with the requirements for the health claim on dietary saturated fat and cholesterol and heart disease (published elsewhere in this issue of the **Federal Register**), is requiring in new § 101.77(c)(2)(ii)(B) that foods bearing the health claim meet requirements for "low saturated fat," "low cholesterol," and "low total" fat, or alternatively, belong to a class of products that is "low in saturated fat," "low in cholesterol," and "low in total fat." Low saturated fat and cholesterol diets are associated with reduced heart disease risk. Low or negligible total fat is also one of the characterizing features of diets rich in fiber-containing fruits, vegetables, and grain products. Because the effects of saturated fat and cholesterol are not readily separated from the effects of other nutritive components of fruits, vegetables, and grain products, and because the scientific evidence linking diets low in saturated fat and cholesterol to reduced risk of heart disease is strong, saturated fat and cholesterol are specified as qualifying nutrients. Total fat is also specified as a qualifying nutrient because a low content of total fat is characteristic of dietary patterns which relate to lower heart disease risk, and because it facilitates the ability of consumers to achieve diets low in saturated fat and cholesterol. (See final rule on "Dietary Saturated Fat and Cholesterol and Coronary Heart Disease," published elsewhere in this issue of the **Federal Register**).

In new § 101.77(c)(2)(ii)(C), FDA is requiring that fruits, vegetables, and grain products bearing the authorized health claim contain at least 0.6 g of dietary soluble fiber per reference amount commonly consumed. Because soluble fiber is a qualifying nutrient, FDA, in new § 101.77(c)(2)(ii)(D), is requiring declaration of soluble fiber content consistent with requirements in § 101.9(c)(6)(i)(A). The qualifying value of 0.6 g of soluble fiber is based on several considerations. First, an expert panel convened by LSRO (Ref. 39)

recommended total dietary fiber intakes of 20 to 30 g daily for adults (see final rule on daily reference values published elsewhere in this issue of the **Federal Register**). It further recommended that approximately 25 percent (or about 6 g) of this be soluble fiber. This level of soluble fiber represents the same ratio of soluble to insoluble fiber normally found in foods and for which there is a long history of use, and therefore was considered by the panel to be safe. Since current U.S. dietary fiber intakes, including soluble fiber intakes, are estimated to be approximately half of the recommended levels, Americans would need to double their intakes to meet the current dietary guidelines. A total daily intake of 6 g of soluble fiber from fruits, vegetables, and grains is consistent with current dietary guidelines for the general population.

The qualifying criterion of 0.6 g per reference amount customarily consumed is also consistent with the definition of a "good source" of a nutrient (i.e., 10 percent of the daily reference value (DRV)) in the final rule on general requirements for nutrient content claims published elsewhere in this issue of the **Federal Register**. Although there is no DRV for soluble fiber, the requirement that a nutrient be present at 10 percent of a reference standard has been set as a qualifying level in other regulations authorizing health claims. (See the final rules on antioxidant vitamins and cancer and on fiber cancer published elsewhere in this issue of the **Federal Register**.) The 10 percent level is deemed useful and appropriate, because very few foods could naturally meet the requirement for a "high" source of soluble fiber. The current dietary guidance recommendations of five or more servings of fruits and vegetables and six or more servings of grain products daily, if followed, would likely result in intakes of soluble fiber close to or exceeding the recommended daily intake of 6 g. Thus, use of a qualifying criterion consistent with that used to define a "good" source for nutrients which have DRV's provides for an amount that allows a number of fruits, vegetables, and grain products to qualify, and is consistent with current dietary guidelines for general dietary patterns. Without this alternate level, very few fruits, vegetables, and grain products would qualify for the health claim, which would be contrary to the available scientific evidence and to the purpose of health claims.

Section 101.77(c)(2)(ii)(C) also requires that foods qualify as a good source of soluble fiber based on their natural level of soluble fiber. This means that foods which require fortification with soluble fiber, in order to meet the qualifying criteria for the health claim, cannot bear the claim. This requirement is consistent with the scientific basis for the claim, that is, that intakes of fruits, vegetables, and grains in their native form correlate with reduced heart disease risk. Because there are not sufficient data that specifically identify dietary soluble fiber, or particular components of soluble fiber, as the cause of a reduction in heart disease risk, and because this nutrient is being used as a marker for the substance or substances in fruits, vegetables, and grain products that provide the observed protective effect, it is the native composition of the foods that identifies their usefulness.

D. Optional Information

Under new § 101.77(d), similarly to other authorized health claims, health claims may identify additional risk factors for heart disease. The regulation specifies the factors that may be listed; all are risk factors about which there is general scientific agreement. This additional information can provide a context that is useful for an understanding of the relationship of the diet to the disease, but manufacturers are cautioned that it should not be presented in a way that is misleading to the consumer. A health claim may also indicate that reductions in saturated fat and cholesterol intake and consumption of fruits, vegetables, and grain products are part of a total dietary pattern that is consistent with the latest "Nutrition and Your Health: Dietary Guidelines for Americans," published jointly by the U.S. Department of Agriculture and the U.S. Department of Health and Human Services. Consistent with other health claim regulations, the claim may also include information on the prevalence of heart disease in the United States. In order to ensure that this information is valid, the agency is requiring that it come from one of three specified authoritative sources. Finally, because consumers frequently know their cholesterol levels or can determine their levels through readily available facilities in shopping malls and health clinics, the agency, similarly to other authorized health claims, is requiring that when information in the claim allows consumers to "self-diagnose" their own risk level, that additionally, the claim indicate the need for medical guidance if a consumer falls within a risk category.

Similarly to the requirements in § 101.73 on "Dietary Saturated Fat and Cholesterol and Coronary Heart Disease," the claim may indicate that the relationship between diets low in saturated fat and cholesterol and high in fruits, vegetables, and grains that contain fiber, particularly soluble fiber, is through the intermediate link of "blood cholesterol" or "blood total- and LDL-cholesterol." Such information is useful to consumers, but could add unnecessarily to the length and complexity of the required health claim. For these reasons, this provision is optional rather than mandatory.

E. Model Health Claims

In new § 101.77(e), FDA is providing model health claims to illustrate the requirements of new § 101.77. FDA is not prescribing specific language for claims, but certain elements are required, and these models include the required elements.

VII. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VIII. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–854), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), and along with the food labeling proposals, the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's

discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act, and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. New § 101.71 is added to subpart E to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(b) Dietary fiber and cardiovascular disease.

3. New § 101.77 is added to subpart E to read as follows:

§ 101.77 Health claims: fruits, vegetables, and grain products that contain fiber, particularly soluble fiber, and risk of coronary heart disease.

(a) *Relationship between diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain fiber, particularly soluble fiber, and risk of coronary heart disease.* (1) Cardiovascular disease means diseases of the heart and circulatory system. Coronary heart disease is the most common and serious form of cardiovascular disease and refers to diseases of the heart muscle and supporting blood vessels. High blood total- and low density lipoprotein (LDL)- cholesterol levels are major modifiable risk factors in the development of coronary heart disease. High coronary heart disease rates occur among people with high blood cholesterol levels of 240 milligrams per deciliter (mg/dL) (6.21 (mmol/L)) or above and LDL-cholesterol levels of 160 mg/dL (4.13 mmol/L) or above. Borderline high risk blood cholesterol levels range from 200 to 239 mg/dL (5.17 to 6.18 mmol/L) and 130 to 159 mg/dL (3.36 to 4.11 mmol/L) of LDL-cholesterol. Dietary lipids (fats) include fatty acids and cholesterol. Total fat, commonly referred to as fat, is composed of saturated fat (fatty acids containing no double bonds), and monounsaturated and polyunsaturated fat (fatty acids containing one or more double bonds).

(2) The scientific evidence establishes that diets high in saturated fat and cholesterol are associated with increased levels of blood total- and LDL-cholesterol and, thus, with increased risk of coronary heart disease. Diets low in saturated fat and cholesterol are associated with decreased levels of blood total- and LDL-cholesterol, and thus, with decreased risk of developing coronary heart disease.

(3) Populations with relatively low blood cholesterol levels tend to have dietary patterns that are not only low in total fat, especially saturated fat and cholesterol, but are also relatively high in fruits, vegetables, and grain products. Although the specific roles of these plant foods are not yet fully understood, many studies have shown that diets high in plant foods are associated with reduced risk of coronary heart disease. These studies correlate diets rich in fruits, vegetables, and grain products and nutrients from these diets, such as some types of fiber, with reduced coronary heart disease risk. Persons consuming these diets frequently have high intakes of dietary fiber, particularly soluble fibers. Currently, there is not scientific agreement as to whether a particular type of soluble fiber is beneficial, or whether the observed protective effects of fruits, vegetables, and grain products against heart disease are due to other components, or a combination of components, in these diets, including, but not necessarily limited to, some types of soluble fiber, other fiber components, other characteristics of the complex carbohydrate content of these foods, other nutrients in these foods, or displacement of saturated fat and cholesterol from the diet.

(b) *Significance of the relationship between diets low in saturated fat and cholesterol, and high in fruits, vegetables, and grain products that contain fiber, particularly soluble fiber, and risk of coronary heart disease.* (1) Coronary heart disease is a major public health concern in the United States, primarily because it accounts for more deaths than any other disease or group of diseases. Early management of risk factors for coronary heart disease is a major public health goal that can assist in reducing risk of coronary heart disease. There is a continuum of mortality risk from coronary heart disease that increases with increasing levels of blood LDL-cholesterol. Individuals with high blood LDL-cholesterol are at greatest risk. A larger number of individuals with more moderately elevated cholesterol also have increased risk of coronary events; such individuals comprise a substantial proportion of the adult U.S. population. The scientific evidence indicates that reducing saturated fat and cholesterol intakes lowers blood LDL-cholesterol and risk of heart disease in most individuals, including persons with blood cholesterol levels in the normal range. Additionally, consuming diets high in fruits, vegetables, and grain products, foods that contain soluble fiber, may be a useful adjunct to a low saturated fat and low cholesterol diet.

(2) Other risk factors for coronary heart disease include a family history of heart disease, high blood pressure, diabetes, cigarette smoking, obesity (body weight 30 percent greater than ideal body weight), and lack of regular physical exercise.

(3) Intakes of saturated fat exceed recommended levels in many people in the United States. Intakes of cholesterol are, on average, at or above recommended levels. Intakes of fiber-containing fruits, vegetables, and grain products are about half of recommended intake levels. One of the major public health recommendations relative to coronary heart disease risk is to consume less than 10 percent of calories from saturated fat, and an average of 30 percent or less of total calories from all fat. Recommended daily cholesterol intakes are 300 mg or less per day. Recommended total dietary fiber intakes are about 25 grams (g) daily, of which about 25 percent (about 6 g) should be soluble fiber.

(4) Current dietary guidance recommendations encourage decreased consumption of dietary fat, especially saturated fat and cholesterol, and increased consumption of fiber-rich foods to help lower blood LDL-cholesterol levels. Results of numerous studies have shown that fiber-containing fruits, vegetables, and grain products can help lower blood LDL-cholesterol.

(c) *Requirements.* (1) All requirements set forth in § 101.14 shall be met.

(2) Specific requirements. (i) *Nature of the claim.* A health claim associating diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain fiber, particularly soluble fiber, with reduced risk of heart disease may be made on the label or labeling of a food described in paragraph (c)(2)(ii) of this section, provided that:

(A) The claim states that diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain fiber "may" or "might" reduce the risk of heart disease;

(B) In specifying the disease, the claim uses the following terms: "heart disease" or "coronary heart disease;"

(C) The claim is limited to those fruits, vegetables, and grains that contain fiber;

(D) In specifying the dietary fiber, the claim uses the term "fiber," "dietary fiber," "some types of dietary fiber," "some dietary fibers," or "some fibers;" the term "soluble fiber" may be used in addition to these terms;

(E) In specifying the fat component, the claims uses the terms "saturated fat" and "cholesterol;" and

(F) The claim indicates that development of heart disease depends on many factors; and

(G) The claim does not attribute any degree of risk reduction for coronary heart disease to diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain fiber.

(ii) *Nature of the food.* (A) The food shall be or shall contain a fruit, vegetable, or grain product.

(B) The food shall meet the nutrient content requirements of § 101.62 for a "low saturated fat," "low cholesterol," and "low fat" food.

(C) The food contains, without fortification, at least 0.6 g of soluble fiber per reference amount customarily consumed;

(D) The content of soluble fiber shall be declared in the nutrition information panel, consistent with § 101.9(c)(6)(i)(A).

(d) *Optional information.* (1) The claim may identify one or more of the following risk factors for heart disease about which there is general scientific agreement: A family history of coronary heart disease, elevated blood-, total- and LDL-cholesterol, excess body weight, high blood pressure, cigarette smoking, diabetes, and physical inactivity.

(2) The claim may indicate that the relationship of diets low in saturated fat and cholesterol, and high in fruits, vegetables, and grain products that contain fiber to heart disease is through the intermediate link of "blood cholesterol" or "blood total- and LDL-cholesterol."

(3) The claim may include information from paragraphs (a) and (b) of this section, which summarize the relationship between diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain fiber and coronary heart disease, and the significance of the relationship.

(4) In specifying the nutrients, the claim may include the term "total fat" in addition to the terms "saturated fat" and "cholesterol."

(5) The claim may indicate that it is consistent with "Nutrition and Your Health: Dietary Guidelines for Americans," U.S. Department of Agriculture (USDA) and Department of Health and Human Services (DHHS), Government Printing Office (GPO).

(6) The claim may state that individuals with elevated blood total- and LDL-cholesterol should consult their physicians for medical advice and treatment. If the claim defines high or

normal blood total- and LDL-cholesterol levels, then the claim shall state that individuals with high blood cholesterol should consult their physicians for medical advice and treatment.

(7) The claim may include information on the number of people in the United States who have heart disease. The sources of this information shall be identified, and it shall be current information from the National Center for Health Statistics, the National Institutes of Health, or "Nutrition and Your Health: Dietary Guidelines for Americans," USDA and DHHS, GPO.

(e) *Model health claims.* The following model health claims may be used in food labeling to characterize the relationship between diets low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain soluble fiber:

(1) Diets low in saturated fat and cholesterol and rich in fruits, vegetables, and grain products that contain some types of dietary fiber, particularly soluble fiber, may reduce the risk of heart disease, a disease associated with many factors.

(2) Development of heart disease depends on many factors. Eating a diet low in saturated fat and cholesterol and high in fruits, vegetables, and grain products that contain fiber may lower blood cholesterol levels and reduce your risk of heart disease.

Dated: November 6, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following table will not appear in the annual Code of Federal Regulations.

BILLING CODE 4160-01-F

Study	Study Design	Subjects	Methods
Anderson et el., 1991 (Ref. 92).	Intervention, parallel, placebo-controlled, randomly assigned to treatment groups after 8 weeks of diet therapy on American Heart Association (AHA) Step 1 diet and stratification by gender and cholesterol level. Purpose of study: to compare hypocholesterolemic effects of two bulk laxatives relative to psyllium and placebo.	163 mild to moderately hypercholesterolemic males and females enrolled in study, 117 completed 8-week diet therapy, and 105 completed the study protocol. Subjects, ages 30 to 70 years, were free living. (total serum cholesterol (TC) 200 to 300 mg/dL and body weight within 130% of ideal.	Subjects consumed AHA s an 8-week adaptation pe by an 8-week parallel t period. Four doses of t were taken each day, in before each meal. Diet 3-day food records at 4 intervals. Step 1 diet: Energy fro 33%; protein--17 to 18% (CHO)--46 to 51%; Chole mg/day. Bulk laxatives tested: psyllium powder (PSY) methylcellulose powder (MC) calcium polycarbophil tablets (CP) cellulose placebo (PLA)

Diet group / SU group TC, mg/dL fiber 278 / 247* control 275 / 275 *significant difference from SU control group.	Cholesterol lowering (10%) only in patients treated with SU. Authors state that hypocholesterolemic effect of this magnitude appears to be common during fiber treatment of NIDDM. Authors also note that another study noted a similar effect of guar in insulin-treated, but not SU-treated patients with NIDDM. They conclude that this suggests that a hypocholesterolemic effect of fiber in NIDDM patients is not linked to the type of treatment but may be explained by patient selection. Beet fiber had no effect on serum triglycerides or in glucose control in this study. No body weight data.

riod. onsumed 20 ounces of a ted juice per day to t, which supplied 10 g ble fiber, rom gum arabic) eceived 20 ounces per emented apple juice. o maintain normal style habits.	With both ordered groups toteled, there is e significent decreese in serum totel cholesterol end LDL-cholesterol during the period of consumption of fiber-enriched juice.	The cholesterol intake was significantly higher in the juice only group. In the group, ordered plain juice, then fiber-enriched juice, there is no change in totel serum cholesterol followed by a significant decreese while on fiber-enriched juice. In the group which was given fiber-enriched juice first, there is a significant decreese while on the fiber-enriched juice, followed by no increese while on plein juice. The euthors attribute this to a carryover effect of the fiber, but this is difficult to sey.

[Docket No. 91N–0100]

RIN 0905–AB67

Food Labeling: Health Claims and Label Statements; Folic Acid and Neural Tube Defects

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision not to authorize a health claim for folic acid and neural tube defects at this time. However, consistent with the recently announced recommendations of the U.S. Public Health Service (PHS) that all women of childbearing age in the United States consume 0.4 milligram (mg) (400 micrograms (µg)) of folic acid daily to reduce their risk of having a pregnancy affected with spina bifida or other neural tube defects, FDA plans to work expeditiously to authorize a claim, if appropriate. At that time the PHS identified several issues that remain outstanding, including the appropriate level of folic acid in food and safety concerns regarding increased intakes of folic acid. Given the significance of neural tube defects and the PHS recommendation, the agency is continuing to address the issues about folic acid. FDA recently convened an advisory committee to consider the outstanding concerns (57 FR 52781, November 5, 1992). The advisory committee provided recommendations to the agency on the following issues: (1) What is the target population for a folic acid neural tube defect health claim? (2) How does the information available on the effective level of intake affect options for implementation? (3) What safety concerns for the target population and for persons in the general population must be addressed? and (4) If a claim is authorized, what is the most appropriate method for presenting it to the target population? The advisory committee's recommendations are currently under FDA review.

EFFECTIVE DATE: May 8, 1993.

SUPPLEMENTARY INFORMATION:

I. Background

A. Procedural Status

In the **Federal Register** of November 27, 1991 (56 FR 60610), FDA proposed not to authorize the use on the label and labeling of foods, including dietary supplements, of health claims relating to an association between folic acid and the reduction in risk of neural tube birth defects. The agency issued this proposal in response to the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) (Pub. L. 101–535). The agency tentatively found that the available scientific evidence showed that daily periconceptional use of 4 mg (4,000 µg) of folic acid, an amount that exceeds the level of 0.4 mg (400 µg) per (/) day permitted under the current food additive regulation (21 CFR 172.345), was needed for reduction in risk of neural tube birth defects in women at high risk of this complication because of a previously affected pregnancy. The agency also tentatively concluded at that time that there was not significant scientific agreement that periconceptional supplementation with doses of folic acid lower than 4 mg/day would significantly reduce the risk of neural tube defects in women of childbearing age in the general U.S. population, who are at much lower risk of an occurrence of this complication.

In September 1992, following an open meeting sponsored by the Centers for Disease Control (CDC) in Atlanta, GA (57 FR 29323) and based on additional reviews of existing data and on new scientific data, the PHS recommended that all women of childbearing age in the United States consume 0.4 mg (400 µg) of folic acid daily to reduce their risk of having a pregnancy affected with spina bifida or other neural tube defects (Ref. 1). In discussing this recommendation, the PHS raised several issues that directly bear on FDA's responsibilities under the Food, Drug, and Cosmetic Act (the act) and the agency's pending rulemaking on whether to authorize a health claim regarding folic acid and neural tube defects. These issues include: (1) Identifying the population at risk, (2) considerations of appropriate level of intake with respect to options for implementation, (3) magnitude of benefit, (4) safety considerations, and (5) identifying the best approach for implementing the recommendation.

The 1990 amendments, in section 3(b)(1)(A)(x), direct FDA to consider whether to grant a health claim for dietary supplements on the effects of folic acid on neural tube defects. Section 3(b)(1)(A)(x) of the 1990 amendments directs the agency to make this judgment based on the standard that FDA is to establish for determining the reliability of health claims for dietary supplements of vitamins, minerals, herbs, and other nutritional substances under section 403(r)(5)(D) of the act (21 U.S.C. 343(r)(5)(D)). In its November 27, 1991 proposal, FDA proposed to adopt the standard that the 1990 amendments provide for conventional foods, which is set forth in section 403(r)(3)(B)(i) of the act, as the standard for dietary supplements. Given this fact, and the fact that folic acid is found in numerous conventional foods as well as in dietary supplements, FDA broadened its inquiry to a determination as to whether it should grant a health claim on folic acid and neural tube defects on any foods.

On October 6, 1992, Congress passed the Dietary Supplement Act of 1992 (the DS Act) which prohibits implementation of the 1990 amendments with respect to dietary supplements of vitamins, minerals, herbs, or other similar nutritional supplements before December 15, 1993. Under the DS Act, FDA may grant health claims for foods, including dietary supplements, using the significant scientific agreement standard specified in section 403(r)(3)(B)(i) of the act. Given this fact and given the breadth of FDA's November 27, 1991 proposal, which included conventional foods as well as dietary supplements, FDA has decided to move forward to determine whether it can authorize a health claim under section 403(r)(3)(B)(i) of the act for folic acid and neural tube defects by resolving the outstanding issues identified in the PHS recommendation (Ref. 1) and in comments to the November 1991 proposal.

With its recommendation, PHS made comments that identified several possible approaches for the delivery of folic acid in the dosage recommended to the general population: (a) Improvement of dietary habits, (b) fortification of the U.S. food supply; and (c) use of dietary supplements. PHS stated that FDA, in deciding whether to authorize a health claim, will have to determine which approaches will best achieve the goal of increasing folic acid intake, while ensuring that potential risks created by overfortification of food with folic acid, and overconsumption of this substance, do not occur.

FDA recognizes that fortification of a wide variety of foods could occur following authorization of a health claim, and that such fortification could lead to a significant increase in the

intake of folic acid by women in their childbearing years as well as by other portions of the general population. Such an increase would bring with it certain risks. The most widely recognized adverse effect of high intakes of folic acid is the potential for progressive neurologic damage resulting from undiagnosed or masked vitamin B_{12} deficiency. This potential risk was recognized by PHS, which stated that because the effects of higher intakes of folic acid are not well known but include complicating the diagnosis of vitamin B_{12} deficiency, care should be taken to keep total folate consumption at less than 1 mg (1,000 µg)/day, except under the supervision of a physician (Ref. 1).

FDA's current food additive regulation for folic acid (21 CFR 172.345) does not include limits on the fortification of specific commodities, and thus, a wide variety of foods could be fortified with folic acid to provide up to 400 µg/day from each source. Such fortification could lead to individual intakes in the range of 3 to 5 mg (3,000 to 5,000 µg) or more of folic acid per day. Thus, there is a significant question as to whether a health claim relating intake of folic acid and reduced risk of neural tube defects, if approved, could be implemented safely.

The requirement that substances eligible for health claims be safe and lawful is included in the final rule for health claims on foods (see General Requirements for Health Claims for Foods, published elsewhere in this **Federal Register**). Sections of the Federal Food, Drug, and Cosmetic Act (the act) enacted by the 1990 amendments cannot be implemented independently of the remaining portions of the act. The act must be considered as a whole, and FDA's responsibility for ensuring the safety of foods is explicitly provided for in other sections of the act (see sections 201(s), 402(a)(1) and (a)(2), and 409, as well as 403(r)(3)(A)(ii) of the act (21 U.S.C. 321, 342(a)(1) and (a)(2), 348, 343(r)(3)(A)(ii))).

The process by which FDA fulfills its responsibilities under the act will require rulemaking. While this process is underway, and before FDA can issue final regulations on fortification of food with folic acid and permissible health claims on foods that contain folic acid, further food fortification with folic acid would be inappropriate; and no health claims should be made (Ref. 1). FDA notes that the PHS recommendation clearly stated that there were risks attendant on overconsumption of folic acid.

B. Neural Tube Defects: Public Health Aspects

As discussed in the proposal (56 FR 60610), several specific malformations of the central nervous system are referred to as "neural tube defects" because the brain and spinal cord develop within the neural tube. The neural tube forms between the 18th and 20th days of pregnancy and closes between the 24th and 27th days. Anencephalus and spina bifida are serious birth defects and account for about 90 percent of neural tube defects. The majority of children with spina bifida survive and have substantial physical disabilities. Most anencephalic infants are stillborn or die shortly after birth. The minimum number of neural tube defect births in the United States is 2,500. This is an underestimate of neural tube defect pregnancies, however, because it does not include neural tube defect pregnancies identified by prenatal diagnosis and electively terminated. Recent data from state-based birth defects surveillance systems show decreasing trends for spina bifida from 1983 to 1990. The combined state rate is 4.6 cases of spina bifida per 10,000 live births (0.046 percent) (Ref. 2).

The multifactorial nature of neural tube birth defects is well recognized (56 FR 60610 at 60611). The single greatest risk factor currently recognized is having a previous neural tube defect-affected pregnancy. Prevalence rates of neural tube defects at birth have been reported to vary with a wide range of factors, including: Genetics, geography, socioeconomic status, maternal birth cohort, month of conception, race, nutrition, and maternal health including maternal age and reproductive history. Certain geographic areas may have, for unknown reasons, considerably higher rates than other areas. For example, a cluster of anencephalic deliveries occurred in the Brownsville, TX area between 1989 and 1991. Investigations of potential causes, including environmental contamination and other factors, are ongoing in this area (Ref. 3).

Maternal health (e.g., febrile illness) and maternal use of certain drugs (e.g., the anticonvulsant drug valproic acid) also contribute to risk of neural tube birth defects. There is an increased incidence of malformations, including neural tube defects, among infants of diabetic mothers. Carriership for an inborn error of homocysteine metabolism has been proposed as a risk factor for having an infant with a neural tube defect (Ref. 4). Poor maternal nutrition, which is among a number of factors associated with poverty, may increase the risk for neural tube defects. A recent case-control study of the cluster of anencephalic deliveries in the Brownsville, TX area found that women with less than a high school education were more than twice as likely to have an infant with a neural tube defect as were women who had finished high school (Ref. 3). This observation correlates with poverty as a known risk factor for neural tube birth defects (Ref. 3).

C. Folic Acid: Regulatory History

1. Drug regulation

The agency evaluated the use of folic acid as a drug in the **Federal Register** of April 9, 1971 (36 FR 6843) in response to reports received from the National Academy of Sciences on the therapeutic uses of folic acid. The agency concluded that folic acid administered orally or parenterally is effective for the treatment of megaloblastic anemias of tropical and nontropical sprue, those of nutritional origin, and those that may occur during pregnancy, infancy, and childhood. The agency found that administration of folic acid alone is improper therapy in the treatment of pernicious anemia and other megaloblastic anemias where vitamin B_{12} is deficient because such treatment may mask the symptoms of vitamin B_{12} deficiency.

In the presence of excess folic acid and inadequate vitamin B_{12}, the anemia of vitamin B_{12} deficiency may not develop, but severe and irreversible nerve damage may continue. Because the anemia of vitamin B_{12} deficiency is frequently the earliest clinical symptom, failure of patients to present with this symptom may unduly delay the diagnosis of vitamin B_{12} deficiency and allow neurologic damage to progress without treatment. The interaction between the functions of folic acid and vitamin B_{12} has been recognized for many years and is the basis for the precautionary statement on preparations of folic acid for therapeutic use.

In the **Federal Register** of April 9, 1971 (36 FR 6843), the agency announced the conditions under which it would approve new drug applications for folic acid preparations. The labeling conditions included the following precaution: "Folic acid especially in doses above 1.0 mg daily may obscure pernicious anemia, in that hematologic remission may occur while neurological manifestations remain progressive."

Based upon the available data and information, in the **Federal Register** of October 17, 1980 (45 FR 69043 at 69044), FDA amended the "Precautions" statement to be included

in the labeling of oral and parenteral preparations of folic acid for therapeutic use because the agency found that the revision more accurately stated the level at which folic acid may obscure pernicious anemia. The **Federal Register** notice stated that "While obscuration of pernicious anemia does not occur at levels of 0.1 mg for folate per day, hematologic remissions in pernicious anemia have been reported at levels as low as 0.25 mg of folate per day. The precautions section of the labeling conditions for folic acid preparations is amended to read as follows: 'Folic acid in doses above 0.1 mg daily may obscure pernicious anemia in that hematologic remission can occur while neurological manifestations remain progressive'."

2. Food additive regulation

Folic acid is an approved food additive subject to the limitations on use set forth in the food additive regulations (§ 172.345). The food additive regulation states that: "Folic acid (folacin) may be safely added to a food for its vitamin properties, provided the maximum intake of the food as may be consumed during a period of 1 day, or as directed for use in the case of a dietary supplement, will not result in daily ingestion of the additive in excess of 0.4 mg for foods labeled without reference to age or physiologic state; and when age or the conditions of pregnancy or lactation are specified, in excess of 0.1 mg for infants, 0.3 mg for children under 4 years of age, 0.4 mg for adults and children 4 or more years of age, and 0.8 mg for pregnant or lactating women" (21 CFR 172.345). However, this regulation provides no limits, other than 0.4 mg, on the amounts that may be provided by specific foods.

In 1981, the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology (FASEB) reviewed evidence concerning effects of physiologic and pharmacologic doses of folic acid in patients with pernicious anemia (Ref. 5). LSRO noted that virtually all of the experimental work reviewed dealt with the administration of pteroylmonoglutamic acid (folic acid) in relatively pure forms. Responses to folic acid in food products are less well defined than responses to a pure preparation. LSRO concluded at that time that it was not possible to answer with certainty whether intakes of folic acid in foods approaching 400 µg (0.4 mg)/day could result in transient hematologic remission in patients with pernicious anemia (Ref. 5).

D. The Proposed Rule

The scientific data relating to an association between folic acid and neural tube defects that was publicly available at the time of publication of the agency's proposed rule (56 FR 60610) consisted of four clinical intervention trials in women at high risk of recurrence of these birth defects (Refs. 6 through 9), four observational studies (Refs. 10 through 13), a number of studies in which clinical parameters such as serum or red blood cell levels of folate and other vitamins were measured in women who gave birth to one or more infants with neural tube defects (Refs. 14 through 17), and studies that attempted to identify factors that may lead to neural tube defects in animal model systems (Refs. 18 through 26).

The agency developed its proposed rule on the basis of the publicly available scientific evidence. An ongoing randomized controlled trial in Hungary of multivitamin/multimineral supplementation of women at risk of an occurrence of a pregnancy complicated by a neural tube defect had been discussed at scientific meetings (Ref. 27), but the scientific data from this trial were not publicly available.

The agency proposed not to authorize the use on the labels and labeling of foods, including dietary supplements, of health claims relating to an association between ingestion of folic acid and reduction in risk of neural tube defects. The agency based its tentative decision on the available scientific evidence, which showed that daily periconceptional intake of 4 mg (4,000 µg) of folic acid was needed for reduction in risk of neural tube birth defects in women at high risk of this condition based on a previously-affected pregnancy. Among women with histories of neural tube defect-complicated pregnancies, rates for recurrence of such defects have been estimated to be as high as 2 to 10 percent compared to occurrence rates of less than 0.1 percent in the general population (Ref. 28). Thus, because of their significantly increased risk, such women have been the focus of several clinical intervention trials. The amount of folic acid found to be effective in reducing risk of recurrence was significantly in excess of usual daily intakes and exceeded the level of 0.4 mg (400 µg)/day permitted under the current food additive regulation. FDA also tentatively concluded that there was not significant scientific agreement that periconceptional supplementation with doses of folic acid lower than 4 mg (4,000µg)/day in women of childbearing age in the general U.S. population would significantly reduce the risk of occurrence of neural tube birth defects. For these reasons, FDA tentatively determined that claims on foods, including dietary supplements, relating to folic acid and reduction in risk of neural tube birth defects were not justified.

E. Recent Developments

1. New scientific data

Preliminary data from the Hungarian randomized, controlled trial of efficacy of multivitamin/multimineral supplements containing 0.8 mg (800 µg) of folic acid in preventing occurrence of neural tube defects were presented at a meeting held in May 1992 (Ref. 29). A report of preliminary results of this trial of the effects of multivitamin/multimineral supplementation in women at risk of a first occurrence of a neural tube birth defect pregnancy became publicly available in August, 1992 (Ref. 30). This trial was conducted under the auspices of the Hungarian Optimal Family Planning Program and was directed toward overall improvement in pregnancy outcomes among Hungarian women. Nonpregnant women 18 to 35 years of age without histories of infertility or previous fetal death volunteered for this program and, upon determination of eligibility, were randomized to treatment with a multivitamin/multimineral preparation containing 12 vitamins and 7 minerals or to a placebo containing 3 trace minerals only. The multivitamin/multimineral preparation contained 0.8 mg (800 µg) of folic acid. The women participated in a 3-month preparation for pregnancy and began taking their assigned treatments 1 month before a planned conception. Treatments continued through the third month of pregnancy. Six cases of neural tube defects occurred in the pregnancies of 2,052 women taking the placebo, and no cases occurred in the pregnancies of 2,104 women taking the multivitamin/mineral supplement with folic acid. Based upon the preliminary results of this study, periconceptional use of a multivitamin/multimineral supplement apparently significantly reduced the rate of occurrence of isolated neural tube defects in women in the Hungarian population. However, use of the supplement did not affect the incidences of a wide range of other birth defects that occurred in both treatment groups (Ref. 30).

Results of a case-control study of periconceptional use of folic acid-containing multivitamins and risk of occurrence of neural tube defects in

women in Boston, Philadelphia, and Toronto were also presented at the meeting held in May 1992 (Ref. 29).

In the **Federal Register** of July 1, 1992 (57 FR 29323), CDC announced an open meeting in Atlanta, GA on July 27, 1992, to discuss a recommendation that all women of child-bearing age in the United States consume 0.4 mg (400 µg) of folic acid daily to reduce their risk of having a neural tube defect-complicated pregnancy. The results of the case-control study of periconceptional use of folic acid-containing multivitamins and risk of occurrence of neural tube defects in women in Boston, Philadelphia, and Toronto were presented at this meeting, and the transcript of the meeting is publicy available (Ref. 31). In this study, 436 occurrent neural tube defect cases (live born and still born cases and therapeutic abortuses) were selected from metropolitan hospitals in Boston, Philadelphia, and Toronto (areas of moderate prevalence) from 1988 through 1991 and compared to 2,615 controls with other major malformations as to maternal periconceptional use of folic acid. Daily use of a folic acid-containing vitamin supplement in the periconceptional period was reported by mothers of 8 percent of cases and 13 percent of controls; the adjusted odds ratio was 0.6 (95 percent confidence interval (CI)= 0.4 to 0.8). This represented approximately a 40-percent reduction in prevalence. A dietary folate assessment was also conducted among the mothers who did not use folic acid-containing supplements. A significant decrease in risk was found for the group who consumed 0.311 to 0.391 mg of folate daily; the adjusted odds ratio was 0.6 (95 percent CI=0.3 to 0.9). The results of this study as presented at the CDC meeting support a relationship between decreased risk of occurrent neural tube defects and periconceptional intake of either folic acid-containing multivitamins or dietary intake of folate at levels of 0.3 to 0.4 mg/day.

2. Reopening of comment period

The period for submitting comments in response to the November 27, 1991, proposal closed on February 25, 1992. In the **Federal Register** of July 23, 1992 (57 FR 32751), however, FDA reopened the comment period to permit the submission of new scientific data and information that might become available as a result of the meeting held by the CDC on July 27, 1992, and to provide an opportunity for public comment on that scientific data and information. The agency took this action, in part, because it had been advised that the scientific evidence to be discussed at the CDC meeting was not publicly available. The 1990 amendments require that the evidence relied upon by the agency as the basis for allowing health claims relating to a nutrient-disease relationship be publicly available.

3. PHS recommendation

In *Mortality and Morbidity Weekly Reports* of September 14, 1992 (Ref. 1), the Public Health Service issued a recommendation that:

> All women of childbearing age in the United States who are capable of becoming pregnant should consume 0.4 mg of folic acid per day for the purpose of reducing their risk of having a pregnancy affected with spina bifida or other NTDs. Because the effects of high intakes are not well known, but include complicating the diagnosis of vitamin B_{12} deficiency, care should be taken to keep total folate consumption at less than 1 mg per day, except under the supervision of a physician. Women who have had a prior NTD-affected pregnancy are at high risk of having a subsequent affected pregnancy. When these women are planning to become pregnant, they should consult their physicians for advice.
>
> (Ref. 1)

PHS noted that the evidence that consumption of folic acid before conception and during early pregnancy (the periconceptional period) can reduce the number of neural tube defects has been accumulating for several years and includes published data from two randomized controlled intervention trials (Refs. 6, 7, and 18), two nonrandomized intervention trials (Refs. 8, 9, and 33), and four observational studies (Refs. 10 through 13). Based on a synthesis of information from these studies, including those which used multivitamins containing folic acid at a daily dose level greater than 0.4 mg, it was inferred that folic acid alone at levels of 0.4 mg per day will reduce the risk of neural tube defects (Ref. 1).

In the discussion accompanying its recommendation, the PHS (Ref. 1) identified several issues that require further attention:

(1) Effective intake: The PHS (Ref. 1) recommended that all women of childbearing age should consume 0.4 mg of folic acid daily to reduce their risk of neural tube defect pregnancies. The PHS (Ref. 1) noted that because supplements containing folic acid at the 0.4 mg (400 µg) level are widely available, this dosage has been the focus of the available observational research studies. PHS also noted that "it is possible that lower doses of folic acid may reduce the risk of neural tube defects, but further research would be needed to learn the minimum effective dose" (Ref. 1).

(2) Multivitamins: The PHS recommendation for the use of folic acid alone was, by necessity, derived by inference from results of the available studies. The Medical Research Council intervention trial included a group of women who used folic acid at a dose of 4 mg per day (plus calcium and iron) and who could be compared with a control group taking calcium and iron only (Ref. 6). Thus, the specificity of folic acid as an etiologic agent in reducing recurrences by 72 percent was established for the study population at this high dose. In contrast, all four observational studies and two of the other three intervention trials measured the use of folic acid-containing multivitamins. Folic acid content and content of other nutrients in these preparations varied, or in some cases, could not be identified (Ref. 1). The preparations used in studies that obtained this information contained (at least) vitamin A, vitamin D, thiamin, riboflavin, pyridoxine, vitamin C, and niacin in addition to folic acid.

Thus, the possibility that nutrients other than folic acid, particularly at intakes of folic acid less than 4 mg daily, could contribute to the protective effect warrants further discussion.

(3) "Folate-preventable" fraction of neural tube defects in the U.S. population: The PHS recommendation recognized that protective effects against occurrence of neural tube defects found in observational studies of multivitamins containing low doses of folic acid have ranged from none to substantial (Ref. 1). Based on the information available, the PHS suggested that a reasonable estimate of the expected reduction in neural tube defects in women in the general U.S. population was 50 percent (Ref. 1).

This issue warrants further discussion because estimates of the magnitude of the preventable fraction and the variation in risks among subgroups of women of child-bearing age may affect decisions as to the best method of implementation.

(4) Safety considerations: The PHS recommendation advised women that care should be taken that folate consumption not exceed 1 mg (1,000 µg)/day except under the supervision of a physician because the effects of higher intakes are not well known (Ref. 1). One of the adverse effects noted was the effect of high intakes on the making a diagnosis of vitamin B_{12} deficiency.

The agency recognizes the risk that increased intakes of folic acid will complicate the diagnosis of the anemia of vitamin B_{12} deficiency and thereby allow the neurological damage caused by this vitamin deficiency to progress

untreated Several other safety considerations are identified below These issues also warrant further discussion as the questions of whether and how to provide for a health claim are evaluated.

II. Comments on the Proposed Rule

A Introduction

The agency received approximately 150 comments in response to its proposed decision on health claims for folic acid and neural tube defects. Comments were received from: Consumers, consumer advocacy groups, national professional organizations of nutrition educators, national professional organizations of dietitians, organizations of Federal, state, and local regulatory officials, state and territorial public health nutrition directors, manufacturers and suppliers of vitamins to the conventional food industry and dietary supplement industry, trade associations of nutritional supplement manufacturers, practicing physicians and dietitians, and a foreign government A number of comments were received that were more appropriately answered in other dockets, and these were forwarded to the appropriate docket for response.

FDA has considered all of the comments on folic acid and neural tube defects that it received The agency reviewed all of the documents, including letters, press releases, scientific articles and data supporting those articles, review articles, and recommendations that were included in the comments A summary of the comments that the agency received and the agency's responses follow:

B Comments

1 Several comments suggested that health claims should be allowed if potential benefits exceed risks, and that FDA should have used a risk/benefit analysis in determining the validity of health claims Other comments stated that supplementation with folic acid is essentially risk-free

FDA disagrees with this comment. Section 403(r)(3)(B)(i) of the act requires that a decision to authorize a health claim be based on the totality of the publicly available scientific evidence and on significant agreement among experts qualified by training and experience to evaluate such evidence that the evidence supports a claim The concept of "no risk" as a justification for a health claim is inconsistent with the requirements of the 1990 amendments. Moreover, there are safety concerns associated with increased intakes of folic acid. These concerns are discussed below.

2. Several comments asked whether studies must be carried out in the United States for health claims. These comments noted that for the calcium/osteoporosis claim, much of the data related to peak bone mass was derived from studies in rural Yugoslavia and found to be "generalizable" to the U.S. population, but for folic acid and neural tube defects, data from non-U.S. populations studies seemed not to be acceptable to FDA. The comment also stated that in rejecting the folic acid/neural tube defect claim, FDA relied heavily on the argument that much of the data was from non-U.S. studies.

In the proposed rule on general requirements for health claims (56 FR 60610 at 60549), FDA stated that consistent results from different types of well-conducted human studies, by different investigators, in different populations would contribute to the totality of scientific evidence from which a valid health claim may be developed. In its November 27, 1991, proposal on folic acid and neural tube defects (56 FR 60610), FDA stated that it was unable to directly apply results from some studies done outside of the United States because these studies were conducted on populations at significantly higher risk than the U.S. population, they lacked adequate control groups, or they were multiply confounded.

FDA participated in the development of the recently published PHS recommendation (Ref. 1). This recommendation relied heavily upon data from other countries and was developed by combining the results from several types of studies carried out in the United Kingdom, Hungary, Cuba, Western Australia, and the United States. Thus, the folic acid rulemaking does not evidence an unwillingness on the part of FDA to consider studies on non-U.S. populations. However, the characteristics of the population at issue may affect the relevance of the study to the FDA's rulemaking.

3. Comments received from state and national professional organizations, an organization of Federal, state, and local regulatory officials, and U.S. state attorneys general were supportive of FDA's proposed rule denying a health claim for folic acid and neural tube defects. One comment stated that the preponderance of scientific literature does not strongly support such a relationship. Another comment recommended that statements regarding the relationship between folic acid and neural tube defects be postponed until further studies have been completed. One comment stated that when the confounding variables relating to the causation of neural tube defects are also considered, the wholesale claim that folic acid supplementation will reduce neural tube defects becomes even more unfounded. Another comment cited the irreversible neurological damage that can result from excess intake of folic acid by persons with undiagnosed pernicious anemia and noted that maternal hyperthermia (for example, from use of hot tubs during the first month following conception) was a recognized risk factor for neural tube defects.

Several comments stated that FDA should allow a health claim that "Folic acid intakes, at about the U.S. RDA level of 400 µg/day, have been associated with significantly lowered risk of severe birth defects, including spina bifida." A consumer advocacy group recommended that a claim for folic acid and neural tube defects be permitted only on supplements containing free folic acid because there is evidence that neural tube defects will be reduced by such supplements. The comment noted further that there is additional evidence that the incidence of neural tube defects may be reduced by food sources of folate, although there is currently no consensus on this point.

These comments raise several important issues. The agency agrees that neural tube defects are multifactorial in nature. A history of neural tube defects is the single greatest risk factor currently recognized. However, the well-conducted Medical Research Council trial (Ref. 6) demonstrated a specific relationship between intake of high doses of folic acid and reduction in risk of recurrence of some neural tube defects in women at increased risk of this complication because of a prior affected pregnancy. The effect of lower doses of folic acid on neural tube defects is less clear. However, based upon a synthesis of information from several studies (including a major study that became available after FDA published its proposal in November, 1991) (Ref. 31), all of which recorded use of multivitamins containing varying levels of folic acid, PHS has recommended that all women of childbearing age consume 0.4 mg (400 µg) of folic acid per day for the purpose of reducing their risk of neural tube defect-complicated pregnancy (Ref. 1).

With regard to the issue of effectiveness of nonsupplement food sources of folate in reducing the incidence of neural tube defects, the agency notes that the vast majority of women do not experience an occurrence of a pregnancy complicated by a neural

tube defect, and the available evidence does not provide clear evidence of the optimum folate intake to prevent this complication. Although the lowest effective dose is not known, the PHS concluded that 0.4 mg (400 µg)/day is an effective dose Dietary folate insufficiency per se does not seem to be causative in neural tube defects. The vast majority of women appear not to be predisposed to have a folate-related neural tube defect pregnancy. Data from the observational study of Milunsky et al., 1989 (Ref. 13) suggested that women whose diets contained more than 100 µg of folic acid had a lower risk of a neural tube defect pregnancy than did women whose diets contained less than 100 µg folate per day. Laurence (1983) (Ref. 32) observed that when dietary counseling to improve overall diets was provided to women at risk of a recurrence of a neural tube defect, and when such improved diets were consumed, risk reduction approached 50 percent. Similarly, a case-control study conducted in Western Australia suggested that diets containing increased amounts of folic acid, vitamin C, beta-carotene, and fiber (nutrients associated with fruits and vegetables), were protective against occurrence of neural tube defects (Ref. 11). Therefore, the agency believes, that with respect to options for implementation, the scientific data provide a basis for further discussion of the appropriate intake and source.

4. Several comments stated that FDA, in developing its proposed rule regarding folic acid and neural tube defects, rejected conclusions of the LSRO report (Ref. 33). Several comments quoted from conclusions of the LSRO report to support a health claim and stated that the conclusions of the LSRO report contributed to the significant scientific agreement that existed regarding the validity of a health claim respecting folic acid and neural tube defects.

The agency contracted with the Life Sciences Research Office of the Federation of American Societies for Experimental Biology (LSRO/FASEB; FDA Contract No. 223–88–2124, Task Order No. 9) to independently evaluate the scientific literature respecting folic acid and neural tube defects. At the time of publication of FDA's proposal in November, 1991, FDA had available a draft copy of the LSRO report "Evaluation of Publicly Available Scientific Evidence Regarding Certain Nutrient-Disease Relationships: 1. Folic Acid and Neural Tube Defects" (Ref. 33). In its proposal (56 FR 60610), FDA noted several concerns with the LSRO report, including its failure to focus on the specific relationship of folic acid to neural tube defects in studies where multiple nutrients were given, or where specific nutrient effects could not be isolated; its failure to differentiate between risk of occurrence and risk of recurrence of neural tube defects; and its failure to differentiate between daily doses of 4 mg (4,000 µg) versus 400 µg in terms of effectiveness in reducing the risk of neural tube defects.

LSRO/FASEB submitted its final report as a comment in February 1992 (Ref. 34). The agency's concerns with the draft report were not addressed in the final LSRO report. Therefore, because the final LSRO/FASEB report did not differ from the draft report available to the agency before publication of its proposal, no change in FDA's tentative conclusion is warranted.

The agency notes, however, that there are significant areas in which the agency's proposed rule and the LSRO/FASEB report (Refs. 33 and 34) are in agreement. For example, the agency is in agreement with the report on the following topics: (1) That 4 mg of folic acid has been demonstrated to have a protective effect against development of neural tube defects, (2) that there is no evidence that the effect of folic acid is long-lasting as a protectant or potential protectant against neural tube defects, (3) that in addition to maternal and fetal nutrition, other individual, dietary, nutrition, and health factors also contribute to the risk of neural tube defects, (4) that there are significant gaps in our knowledge of the etiology of neural tube defects and of how folic acid either alone or in conjunction with other vitamins may protect against neural tube defects, and (5) that it is currently unknown whether neural tube defects are caused by a gene-dependent or drug-induced vitamin dependency requiring a higher than physiological intake of folic acid or other micronutrient.

5. Several comments stated that following publication of the results of the Medical Research Council's trial in July 1991 (Ref. 6), significant scientific agreement emerged concerning the importance of folic acid for the prevention of neural tube birth defects.

FDA agrees that the Medical Research Council's randomized double-blind multicenter trial (Ref. 6) clearly found a significant reduction in recurrence rate of neural tube defects in women supplemented periconceptionally with 4 mg folic acid/day. No protective effects of vitamins other than folic acid were observed. The Medical Research Council's study established a specific role for folic acid in reduction in risk of recurrence in a significant proportion of women at high risk of this complication because of a history of neural tube defect pregnancies. This study did not investigate the efficacy of doses of folic acid lower than 4 mg (4,000 µg) per day. Based on a synthesis of available studies, however, including preliminary results of the Hungarian intervention trial, the PHS has inferred that a lower intake of folic acid will reduce the risk of occurrence of neural tube defects. However, a number of concerns have arisen with respect to the effects of a folic acid health claim that must be resolved before such a claim can be authorized.

6. A number of comments identified options for implementing a health claim, suggested means by which the folate status of the population can be improved, recommended daily doses of folic acid lower than 400 µg, identified safety concerns, or expressed concerns about the current food additive regulation on folic acid. Because these comments largely address the issues raised as needing resolution in the discussion accompanying the PHS recommendation (Ref. 1), FDA believes that it is useful to summarize these comments. However, given the ongoing nature of this rulemaking process, responses to these comments are not possible now but are likely to emerge as the process proceeds.

1. Proposed criteria for health claims and use of the food additive regulation

Several comments stated that the agency should establish criteria for foods or supplements making folic acid claims and proposed such criteria. For example, a comment suggested that requiring foods and supplements to contain more than 20 percent of the reference daily intake would be inappropriate because the widespread fortification of foods might lead to excessive folacin intakes. The comment further suggested that the agency monitor folacin intakes closely after health claims for folic acid appear in the marketplace to determine whether the public is ingesting levels that greatly exceed or fall short of the recommended daily intake of 400 µg. The comment recommended that if the agency found that excess intakes of folic acid posed a risk, it could restrict either the number of foods or supplements to which the vitamin could be added or the maximum levels allowed in foods or supplements, according to the food additive regulation for folic acid. Alternatively, the comment suggested that FDA could lower the minimum folic acid content of foods or

supplements that are allowed to make health claims

FDA intends to review the question of the appropriate level of folic acid in food However, the agency notes that the nature of the rulemaking process, particularly the formal rulemaking process applicable to food additives, does not provide the flexibility or responsiveness envisioned by the comment

Another comment stated that the agency should require full and nondeceptive health claims concerning neural tube defects and folic acid so that consumers are not misled into believing that folic acid might prevent all neural tube defects or reduce the risk of nonneural tube defect birth defects. The comment emphasized that the agency should ensure that claims on folic acid-containing supplements provide full and nondeceptive information. The comment stated that a nondeceptive claim would state that: (a) Folic acid reduces the risk of only neural tube birth defects; (b) scientists estimate that folic acid-intakes may prevent only half of neural tube defects; (c) consuming more than 400 µg (0.4 mg) of folic acid daily will not necessarily provide additional protection against birth defects; and (d) scientists have not fully evaluated the safety of doses higher than 800 µg (0 8 mg).

The act requires that claims on foods must be truthful and not misleading. The failure to disclose material facts would render a claim misleading under section 403(a) of the act. The agency agrees that, based on the results of the Medical Research Council trial (Ref. 6), the association between folic acid intake and birth defects is specifically related to neural tube defects. This trial also found that folic acid, while significantly reducing the risk of neural tube defects in women at high risk of recurrence of this complication, did not significantly alter the incidences of a wide variety of other birth defects in the population studied. Therefore, in deciding whether to authorize a health claim, the agency will consider whether such a claim should specifically state that the only types of birth defects for which an association with folic acid has been identified are neural tube defects, such as anencephaly, spina bifida, and anencephalocoele.

2. Effective intake

One comment stated that better information on the lowest effective level of folic acid is desirable in order to provide as strong a basis as possible for a food fortification program. Another comment noted that the available data suggest that the recommended level of 400 µg of folic acid/day is probably considerably higher than is actually needed to achieve protection. Several comments suggested that a daily dose of 0.2 mg folate (200 µg) was probably adequate for reduction in risk of neural tube defects, and that data from older as well as more recent studies support such a conclusion. Several comments stated that the consideration of efficacy of lower doses is important because there are uncertainties as to whether daily supplements of folic acid plus iron can reduce zinc absorption and result in intrauterine growth retardation in pregnant women.

The question of effective intake was highlighted by PHS This issue was addressed by the advisory committee that FDA convened. Although PHS acknowledged that there may be a lower dose that is effective, it concluded that all women who could become pregnant should ingest 0.4 mg of folic acid daily to reduce their risk of having a pregnancy affected with a neural tube defect (Ref. 1).

3. Specific safety issues

Another comment observed that widespread fortification of the food supply could result from authorization of a health claim as products added folate in order to claim that they were useful in reducing the risk of neural tube defects. The comment noted that following such fortification, the usual intake of folic acid by the U.S. population would rise from about 250 µg/day/person to about 3 to 4 mg (3,000 to 4,000 µg)/day/person, and that the safety of such an outcome is by no means clear. The comment identified large segments of the population with low vitamin B_{12} status and mentioned the potential for development of neurological deficits in such persons as a result of a food supply highly fortified with folic acid. The comment urged the agency to delay action until a full public airing permits a review of all of the implications of each approach to policy in this and related areas. One comment stated that the proposed intake of 0.4 mg (400 µg) should be evaluated in subjects with low zinc status because findings from the United States, Sweden, and Britain suggest that low zinc status is much more common in pregnancy than has been previously suspected, and that zinc deficiency is a known cause of neural tube defects in animal model systems. The comment cited several references that reported that folate can interfere with the utilization of dietary zinc.

These issues were considered by the advisory committee that FDA convened and by the agency in reaching a final decision in this matter

4. Options for implementation

One comment noted that while the quickest and easiest approach to increasing the folate intake of women of reproductive age is to encourage the consumption of folic acid supplements, compliance with such a program would be poor. The comment noted that many adolescent women refuse to use birth control even when provided free of charge and choose not to protect themselves against life-threatening diseases, such as acquired immunodeficiency syndrome (AIDS). Several comments observed that because of the higher rates of neural tube defects among women from lower socioeconomic status groups, alternatives to a "one-a-day" pill method of implementation should be considered. Several comments recommended that fortification of a staple food would likely reach greater numbers of women than would programs utilizing the pill approach. One comment stated that food fortification would require careful documentation of population distributions of consumption of the designated foodstuffs by age, gender, and socioeconomic status. Several comments also included references dealing with the folate status of specific subgroups of the U.S. population and suggested that fortification of staple foods in the food supply would be an appropriate method of improving folate status. The comment noted groups within the population identified in surveys or in clinical studies as at potential risk of folate deficiency include children, adolescents, adults (including pregnant women), and the elderly who could also benefit from folate fortification. Comments also identified other segments of the population at risk of low folate status as those who use alcohol, oral contraceptives, antifolates, and specific nonsteroidal anti-inflammatory drugs.

Again, the comments parallel concerns that were raised by PHS. They will be fully addressed by the agency in deciding, if a health claim is authorized, what is the most effective method of presenting the claim to the U.S. public.

III. Review of the Recent Scientific Literature

In addition to its evaluation of all comments received in response to its proposed rule regarding folic acid and neural tube defects, FDA, using the same criteria identified in the proposal (56 FR 60610 at 60614), also reviewed the scientific literature, including

human studies and studies in animal model systems, that has become publicly available since publication of its proposed rule relative to the relationship between folic acid and neural tube defects.

A. Human Studies

1. Laurence (1991) (Ref. 35) reported the results of an uncontrolled folic acid supplementation trial in women who had a previous pregnancy complicated by a neural tube defect. Women in Cardiff, United Kingdom, at recurrent risk of a neural tube defect pregnancy and who declined to participate in the Medical Research Council trial (Ref. 6) were advised to take a supplement containing 4 mg folic acid and minerals for not less than 1 month before conception and continuing until 12 weeks of gestation. Laurence (1991) (Ref. 35) reported that there were two (2) recurrences of neural tube defects among 234 pregnancies (recurrence risk of 8.5 per 1,000) in the supplemented women. The estimated risk for recurrence among untreated women (none were included in the trial) was about 30 per 1,000. Laurence (1991) (Ref. 35) estimated that the folic acid plus minerals supplementation reduced the risk of recurrence of neural tube defects by more than two-thirds. The author noted that although this was an uncontrolled trial, folic acid should be offered to all high risk women planning further pregnancies.

2. Measurement of maternal or fetal blood levels of specific vitamins is one method used to test the hypothesis that folic acid status is directly related to risk of neural tube defects. Several investigations have tested this hypothesis by determining whether occurrence of neural tube defects is associated with decreased maternal levels of vitamins (Refs. 14 through 17). A recently reported study, Holzgreve et al. (1991) (Ref. 36), found no differences in serum and erythrocyte folate in blood samples from fetuses with neural tube defects (n=17) or fetuses without such defects (n=45). Samples were obtained at 16 to 22 weeks of gestational age. The folate level of women pregnant with a neural tube defect-affected fetus was normal, and nutritional status did not differ between the two groups. The authors noted that their findings of no correlation between neural tube defects and fetal blood folate values do not necessarily contradict the Medical Research Council study (Ref. 6) but show that an easy explanation for the protective effect of folate observed in the British study cannot as yet be provided. The authors also stated that further research is needed to define the role of micronutrients in the development of neural tube defects.

3. The results of the Medical Research Council trial (Ref. 15) demonstrated that women at very high risk of having a recurrence of a neural tube defect-complicated pregnancy could significantly reduce their risk by taking a high level of folic acid periconceptionally. Other investigators have attempted to determine how these results might apply to a general population of women at much lower risk of occurrence of neural tube defects. Mills et al. (1992) (Ref. 37) measured levels of folate, vitamin B_{12}, and retinol in maternal serum samples drawn early in 89 pregnancies resulting in neural tube defect offspring and in 178 control pregnancies. Samples were obtained within 8 weeks of neural tube closure. The results of this population-based study in Finland, a low prevalence area for neural tube defects, demonstrated no relationship between maternal serum folate, vitamin B_{12}, and retinol during pregnancy and the risk of neural tube defects.

B. Animal Studies

Studies with animal model systems are one of several lines of evidence that are used to establish associations between various nutrients or toxicants and birth defects. The relationship between folate deficiency and the incidence of neural tube defects in experimental animal model systems is not clear. A variety of protocols have been used to study the relationship between nutritional status and risk of neural tube defects (56 FR 60610). The anticonvulsant drug valproic acid is suspected of causing neural tube defects in humans. The mechanism for such effects is unknown but has been postulated to involve induction of a deficiency of folic acid. Hansen and Grafton (1991) (Ref. 38) examined this possibility by culturing rat embryos concurrently in valproic acid and folinic acid, a folic acid derivative. The authors reported a dose-related increase in the number of open neural tubes in rat embryos cultured in valproic acid. When various concentrations of folinic acid were added in combination with a teratogenic dose of valproic acid, there was no decrease in the incidence of open neural tubes. The results of this study suggested that valproic acid-induced open neural tubes in this experimental animal model system are not the result of a deficiency of folic acid.

However, Wegner and Nau (1991) (Ref. 39) also studied the protective effects of folinic acid against valproic acid-induced neural tube defects in the mouse and reported a different result. These authors observed significant diurnal variations in folate metabolism in mouse embryos between days 8.5 and 9.5 of gestation. They measured significant time dependent protective effects against valproic acid-induced teratogenesis such that folinic acid reduced neural tube defects when provided at one time period but not when provided at another time period. Such findings indicate the extreme sensitivity of developing embryonic tissue to external factors and are of importance in considering interactions of drugs with folate metabolism as a possible mechanism of teratogenesis (Ref. 39).

Other investigations have sought to determine whether mice deficient only in folic acid produce embryos with neural tube defects. For example, Heid et al., 1992 (Ref. 40) used folate-free amino acid-based diets for producing well-defined dietary concentrations of folic acid for rats and mice. Heid et al (Ref. 40) reported that when Swiss-Webster mice were fed inadequate dietary folic acid, fewer and smaller embryos (that developed normally) were produced during pregnancy. Their studies indicated that folate deficiency alone is insufficient to produce neural tube defects in Swiss-Webster mice.

C. Authoritative Statements

1. Institute of Medicine, National Academy of Sciences

In 1990, the Institute of Medicine of the National Academy of Sciences published its report, "Nutrition During Pregnancy" (Ref. 28). The Institute of Medicine updated this report in 1992 (Refs. 41 and 42) to reflect new data (primarily the results of the Medical Research Council trial; Ref. 6) that had become available since the first publication of the report. Data from the Hungarian randomized intervention trial were not publicly available at the time the report was updated. The report noted that a previous history of a neural tube defect should alert health care providers to the need for preventive measures before a subsequent pregnancy. The report recommended that women with a history of neural tube defect-complicated pregnancy follow the CDC recommendations (Refs. 41 and 42) for high-dose folic acid supplementation (preconceptionally and throughout the first trimester, under a physician's supervision) to reduce their risk of recurrent neural tube defects (Refs. 41 and 42). The report noted that questions remain concerning the etiology of neural tube defects, the most appropriate dosage, and the

appropriate role of nutrition in preventing first occurrences.

2. World Health Organization

That there is still considerable uncertainty as to how best to reduce the risk of neural tube defects is shown by information in a recently published "World Health Organization (WHO) Drug Information Bulletin" (Ref. 43). The bulletin notes that an expert advisory committee has now been set up in the United Kingdom to consider how best to ensure that all women likely to become pregnant receive supplementary folic acid (Ref. 44). The WHO Bulletin states "Unfortunately the available data provide no indication of how long supplementation needs to be continued to obtain the maximum effect, or of whether the same protective effect can be obtained with lower doses. These are matters of some importance because it may be impracticable to supply a supplement of 4 mg daily from dietary sources alone. Some empiricism will be required to arrive at a recommendation. Short of conducting a further trial with different dosage regimens, formal demonstration of a dose-effect relationship will remain outstanding" (Ref. 43). FDA notes that data from the Hungarian intervention trial were not publicly available at the time this statement was prepared.

D. Conclusions from the Recent Scientific Literature

The recent scientific literature, including studies in humans and animals, is consistent with PHS recommendation and raises a number of issues that PHS noted as needing resolution.

IV. Actions on Folic Acid

A. Determination That No Claim Can be Authorized at This Time

Section 403(r)(3)(B)(i) of the act states that FDA is to grant a health claim when there is significant scientific agreement that the scientific data relating a nutrient to a disease or health condition supports such a claim. The recent PHS recommendation (Ref. 1) evidences that such agreement exists. However, the Food, Drug and Cosmetic Act must be read as a whole.

Sections 403(r)(3)(A)(ii), 402(a), and 409 of the act express the proposition that the use of a substance in food must be safe. As the PHS recommendation states (Ref. 1), there are significant questions that persist about the use of folic acid in food. Questions raised in the PHS recommendation (see section I.E.3. of this document) include the safety of high intakes by both the target population as well as by other segments of the population who may unintentionally be exposed to high intakes if overfortification of the food supply were to occur as a result of the PHS recommendation. There are, additionally, several other unresolved scientific questions that will require discussion before a claim is authorized.

Based on these concerns, FDA concludes that under section 403(r)(3) of the act, it cannot authorize a health claim on folic acid and neural tube defects. FDA is concerned that the possibility exists that folic acid itself could be a substance that increases the risk of a disease or a health-related condition in persons in the general population (see section 403(r)(3)(A)(ii) of the act). Therefore, FDA concludes that it cannot authorize a health claim on folic acid until the questions regarding the safety of the use of this nutrient as well as the other concerns raised by PHS are satisfactorily resolved. However, the agency is undertaking efforts to address and resolve these concerns. The remainder of this document outlines how the agency will do so.

B. Issues

1. Estimation of range of increased intakes

FDA expects that there would likely be a significant increase in consumption of folic acid by women in their childbearing years, and by the general population, if a health claim were to be authorized because manufacturers would add folic acid to their products in order to claim that these products are useful in reducing the risk of birth defects. Intakes of multiple doses of free folic acid in the form of supplements and from its increased presence in the food supply could rapidly result in intakes of more than 3 mg (3,000 µg)/day by persons in the target population as well as by persons in the general population (see Table, Estimate A). Considerably higher amounts of folic acid (approximately 7 mg (7,000 µg)/day) could be consumed by subgroups of the population (e.g., teen-age and young adult males, heavy users of supplements) (see Table, Estimate B).

a. *Differences in bioavailability between free folic acid and food folates.* It is well-recognized that the bioavailability of free folic acid (the form included in dietary supplements and in fortified foods) is several-fold greater than that of naturally occurring food folates. Estimates of the increased bioavailability ("potency") of free folic acid relative to food folates range from at least 2-fold to 4-fold or greater (Ref. 45). The pronounced differences in bioavailability between free folic acid and food folates must be factored into considerations of appropriate dose as well as considerations of potential safety issues.

b. *History of use.* Because the National Research Council recommended daily allowances have been set below 500 µg of food folates ("folacin") (except those for pregnant women) since 1968 (Refs. 46, 47, and 48), and because the food additive regulation has limited the amount of free folic acid added to fortified foods and supplements to 400 µg/day (except supplements for pregnant or lactating women), there is no history of long-term use by persons in the general U.S. population, including pregnant women, of daily intakes of free folic acid in excess of about 1 mg (1,000 µg). Therefore, potential safety concerns must be addressed.

2. Specific safety issues and estimates of magnitude

If a wide variety of food sources were fortified with 400 µg folic acid/serving, as would likely occur following authorization of a health claim, intakes of folic acid could easily reach 3 mg (3,000µg)/day or higher. FDA's concerns regarding large increases in folic acid fortification, and the large increases in intake that would result, are summarized below.

a. *Vitamin B_{12}*-related issues. (i) Issue: As mentioned above, in the presence of excess folic acid and inadequate vitamin B_{12}, the anemia of vitamin B_{12} deficiency may not develop but severe and irreversible nerve damage may continue. This interaction between the functions of folic acid and vitamin B_{12} has been recognized for many years and is the basis for the precautionary statement on oral and parenteral preparations of folic acid for therapeutic use in treating folate-deficiency anemias. The agency is reviewing the literature upon which this concern is based.

In 1945, folic acid was introduced as a possibly specific substance for the treatment of pernicious anemia. A large number of reports based on small numbers of cases studied for short periods of time followed the introduction of this new therapy (Ref. 49). It was soon recognized that the two manifestations of pernicious anemia (the hematologic disturbances and the neurologic disturbances) responded differently to therapy with folic acid. Reports began to appear in the literature calling attention to the deleterious and sometimes "explosively" harmful effects of folic acid on the neurologic

manifestations of the disease (Refs. 50 through 53).

There is ample evidence that most patients with pernicious anemia respond hematologically to folic acid (Refs. 54 through 59). Doses of 1 to 5 mg folic acid can reverse the hematologic abnormalities of the deficiency (Refs. 60 through 64). Hematologic improvement in pernicious anemia has also been noted at doses of folic acid lower than 1 mg (e.g., 200 to 500 µg) (Refs. 58, 59, 65 through 67, and 100), but the responses have been less predictable than those to doses of 1 to 5 mg. For example, Chosy et al. (1962) (Ref. 66) reported that daily injections of 400 µg of folic acid caused hematologic responses in some patients with pernicious anemia. Some investigators have not been convinced that amounts of folic acid within the range of 200 to 500 µg/day would mask pernicious anemia (Refs. 65, 68, and 101), while others have reported suboptimal responses to 500 µg of folic acid in patients with pernicious anemia (Refs. 58 and 59).

On the basis of the degree of reticulocyte response, 200 µg folic acid has been used to differentiate between the megaloblastic anemias caused by folate deficiency and vitamin B_{12} deficiency (Ref. 69). Chanarin (1969) (Ref. 69) cautioned that this use should not be interpreted to mean that long-term administration of 200 µg of folic acid could not mask pernicious anemia in some otherwise untreated patients. Herbert (1975) (Ref. 70) and Herbert et al. (1980) (Ref. 71) recommended that 100 µg folic acid be administered orally in therapeutic trials. This dosage has been shown to provide a maximal hematologic response in patients with folate deficiency but not in those with vitamin B_{12} deficiency (Ref. 72). This finding is in agreement with the statement of Chanarin (1969) (Ref. 69) that doses of folic acid greater than 200 µg/day might produce hematologic responses in some patients with pernicious anemia.

Pernicious anemia is not an insignificant or rare condition in the United States (see section IV.B.2.a.ii. of this document), nor is its diagnosis always straightforward. For example, Lindenbaum et al. (1990) (Ref. 73) has reported that while serum cobalamin levels have been generally considered to be essentially 100 percent sensitive in the detection of clinical disorders caused by cobalamin deficiency, there is a significant minority of patients with cobalamin deficiency whose serum cobalamin levels are normal. In such individuals, measurements of serum metabolite concentrations of methylmalonic acid and total homocysteine may be necessary to facilitate the diagnosis of vitamin B_{12} deficiency (Ref. 73).

In summary, the available evidence indicates that some patients with pernicious anemia will respond to folate therapy in doses less than 500 µg/day. Other individuals with pernicious anemia will not exhibit hematologic remission at such doses but will respond to doses of 1 mg of folic acid and higher. It is not possible to answer with certainty whether intakes of folic acid in foods approaching 400 µg/day could result in transient hematologic remission in patients with pernicious anemia. The agency believes that this issue warrants further discussion.

(ii) Estimates of magnitude: Vitamin B_{12} deficiency anemias are not uncommon in the U.S. population. Information from the National Center for Health Statistics indicates that there were 740,000 patient visits to physicians' offices with a diagnosis of pernicious anemia during the 2-year interval 1989 to 1990 (Ref. 74). Approximately 524,000 of these visits were by women (Ref. 74). An additional 16,000 patient visits during this interval involved a diagnosis of other vitamin B_{12} deficiencies (for example, those associated with consumption of vegetarian diets).

National Center for Health Statistics records from the National Hospital Discharge survey for 1990 identified 31,000 discharges that included a diagnosis of pernicious anemia and an additional 7,000 discharges that included a diagnosis of other vitamin B_{12} deficiency anemia (Ref. 75).

It is recognized that among African-Americans, particularly African-American women, pernicious anemia is not confined to the elderly, as it generally is among whites (Refs. 76 through 78). Thus, a large subgroup of young African-American women in the general population may be especially vulnerable to adverse effects of significantly increased intakes of folic acid.

Although the number of "visits" recorded in the ambulatory care surveys mentioned above include multiple visits by some patients, the data show that pernicious anemia is not an insignificant or rare condition in the U.S. population. There is currently no way to determine how many persons in the general U.S. population have undiagnosed vitamin B_{12} deficiency. A large number of people have subnormal levels of serum vitamin B_{12} without having any classical manifestations of vitamin B_{12} deficiency (Refs. 79 and 80). Ten to twenty percent of elderly persons, more than 25 percent of demented patients, 15 to 20 percent of AIDS patients, and 15 to 20 percent of patients with malignant diseases have low serum vitamin B_{12} levels. In addition, 5 to 10 percent of all patients, regardless of age or clinical status, are found to have low serum B_{12} levels. Metabolic and subtle neurologic dysfunction are demonstrable in a significant fraction of such cases (Ref. 79). Very little is known about whether folate supplementation has any effect on such persons, who are more numerous in the population than are patients with pernicious anemia (Ref. 79). This issue requires consideration in assessing the potential impact of increased intakes of folic acid.

b. *Risks to pregnant women.* In "Nutrition During Pregnancy," the Institute of Medicine (IOM) stated that the safety of large doses of folic acid during pregnancy has not been systematically determined (Ref. 28). The IOM noted that large doses of folic acid may inhibit the absorption of other nutrients by competitive interaction and can also obscure the diagnosis of onset or relapse of pernicious anemia which is extremely rare in women of childbearing age. The IOM recommended modest supplementation for some segments of the U.S. population at risk of folate inadequacy. Such subpopulations include some pregnant women who lack the knowledge or financial resources to purchase adequate food, abusers of alcohol, cigarettes, or drugs, those with malabsorption syndromes, pregnant adolescents, and women bearing more than one fetus. Based upon data available at the time, the IOM recommended 300 µg folate daily during pregnancy for such subpopulations (Ref. 28).

(i) Issue. A potential risk of increased folic acid supplementation involves effects of high blood levels of free folic acid on the embryo during early gestation. The Medical Research Council study that treated women at high risk of a recurrence of a neural tube defect pregnancy with 4 mg folic acid daily did not have the power to ascertain the safety of such high level supplementation in the population studied. This concern was stated by the study's author (Ref. 6). The agency noted above that there is no history of long-term use in the United States of folic acid at levels at or above about 1 mg/day.

(ii) Estimate of magnitude. About 4 million pregnancies occur in the United States each year. The concern regarding the lack of safety data for high doses of folic acid in pregnant women has been

discussed in the scientific literature since the report of the successful Medical Research Council trial (Ref. 6). For example, Leeming et al. (1991) (Ref. 81) stated that while 4 mg of folic acid until 12 weeks of pregnancy may reduce the incidence of neural tube defects in women at high risk of recurrence, there may also be damaging effects. These authors suggested that substantial amounts of unmetabolized folic acid appear in the plasma after a single high dose and suggested that high circulating levels of folic acid may damage developing neural tissue during early embryonic development. They further noted that high levels of folic acid are not normally found in the circulation. Scott et al. (1991) (Ref. 82) also suggested the seriousness of risk during early embryonic development. They stated that while the fully developed brain may be protected from neurotoxic effects of high circulating levels of folic acid, no information is available as to whether developing neural tissue is similarly protected.

c. *Persons with epilepsy* (i) Issue. The possibility has been raised that folic acid supplements in high doses may reverse the effectiveness of anticonvulsant medication (Ref. 83). Folic acid and certain anticonvulsants compete with each other for receptors on brain cells. A potential concern is whether high intakes of folic acid exacerbate seizures in persons with uncontrolled or with drug-controlled epilepsy.

(ii) Estimates of magnitude. There are an estimated 200,000 persons in the United States whose epilepsy is not controlled. Most studies on the effects of folic acid in persons with drug controlled epilepsy have involved institutionalized individuals and responses to increased intakes have been variable.

d. *Persons taking drugs that interfere with folate metabolism.* (i) Issue. Folate antagonists such as Methotrexate are used in the treatment of various cancers, including leukemias (Ref. 84). In addition, low doses of Methotrexate are currently used in the treatment of psoriasis, rheumatoid arthritis, and bronchial asthma. The antifolate Trimethoprim is used to treat bacterial infections. Other therapeutic drugs that interfere with folate metabolism include: Pyrimethamine, Triamterene, sulfasalazine, colchicine, phenyltoin, and Trimetrexate (Ref. 84). Recognition of the therapeutic usefulness of these antifolate drugs for the conditions above has developed during the last 30 years.

(ii) Estimates of magnitude. The drugs mentioned above are used in the treatment of: Psoriasis, rheumatoid arthritis, bronchial asthma, malaria, hypertension, Crohn's disease, gout, epilepsy, and AIDS. Taken together, many of these conditions affect significant portions of the general U.S. population.

The safety of significantly increased folate intakes by persons with these disorders, whether or not they are receiving antifolate medications, remains an open question (Ref. 85). The safety or toxicity of oral folic acid supplements in persons who are being treated with drugs known to interfere with folate metabolism requires further discussion.

It is not known whether substantially increased intakes of folic acid would impair (or reverse) the therapeutic effectiveness of these medications. It is known, for example, that "rescue" by 5-formyl-tetrahydrofolate (a biologically active reduced folate derivative that can compete with antifolate compounds and does not require the activity of the enzyme dihydrofolate reductase for conversion to an active form) is used in patients undergoing chemotherapy with the antifolate Methotrexate. Treatment with 5-formyl-tetrahydrofolate is used to reduce the toxicity of Methotrexate and to protect nonmalignant cells (for example, those in the intestinal tract) from damage by the chemotherapeutic agent.

3. Identifying and targeting the population at risk

a. *The target population.* Given the absence of biological markers to identify women at greatest risk of a neural tube defect pregnancy, a very large population of women must be reached in attempts to reduce the risk of neural tube defects. There are about 70 million women of reproductive age in the United States, of whom about 2,500 annually will have a pregnancy complicated by a neural tube birth defect. As noted above, this number is an underestimate of the number of neural tube defect pregnancies that occur. The safety issues show the importance of the method of implementation chosen to reach the target population. Fortification of the food supply, for example, would expose more than 250 million people to increased folic acid intakes to reach the approximately 4 million women who become pregnant each year. Use of supplements, while potentially capable of targeting some of the population at risk, would not likely reach those of lower socioeconomic status or noncompliers who might also be at increased risk.

b. *Estimation of the "folic acid-preventable" fraction of neural tube defects.* The folic acid-protective effects against risk of neural tube defects found in studies of folic acid at levels lower than 1 mg/day have ranged from none to substantial (Ref. 1). In general, observational studies in areas of moderate prevalence (2–5 neural tube defects/1,000 births) have found protective effects, while a study in two areas of lower prevalence (less than 1 neural tube defect/1,000 births) found no protective effect. While such considerations should not negate an appropriate recommendation for women of child-bearing age, the magnitude of the preventable fraction may influence decisions on how best to implement the PHS recommendation and thus whether and how to provide for a health claim.

4. How does the available information on effective levels of intake affect options for implementation

The neural tube forms and closes during the first month after conception before most women are aware of their pregnancy. For this reason, and since more than half of the pregnancies in the United States are unplanned (Ref. 119), the PHS recommendation stated that it would be prudent for women to consume 0.4 mg of folic acid daily on a regular, continuous basis as long as they are capable of becoming pregnant (Ref. 1).

In the supplementary information accompanying its recommendation, the PHS noted that it is possible that lower intakes of folic acid may reduce the risk of neural tube defects, but that further research would be needed to learn the minimum effective level (Ref. 1). This issue is of importance not only because supplement doses lower than 0.4 mg (400 µg) have not been studied adequately, but because of the unknown contribution of dietary intake to the results reported in the available studies. Most of the studies of supplement use have not evaluated folate intake from foods. Thus, the base of dietary folate intake to which a folic acid-containing supplement was added is unknown. This complicates assessment of intake-response relationships.

Consideration of the minimum effective level of intake is also relevant because of the need for women to maintain good folate nutriture at least 1 month before conception and through the first 6 weeks of pregnancy. Given this fact and the high rate of unplanned pregnancies in the United States, women potentially must consume an effective amount of folic acid during all or most of their child-bearing years. This represents 30 years or more of chronic exposure for the target population. If the minimum effective

level is added to the conventional food supply, it represents a lifetime of exposure for the entire population.

The best available studies used daily intakes of folic acid of 0.8 mg (800 µg) or 4 mg (4,000 µg). These levels are outside of the range of folate provided by usual U.S. diets (100 to 500 µg/day). For example, the well-conducted Medical Research Council trial demonstrated that 4 mg of folic acid daily during the periconceptional period was effective in women at high risk of a recurrence of a neural tube defect-affected pregnancy (Ref. 6). Preliminary data from the recently closed Hungarian trial in women at risk of occurrence of a neural tube defect pregnancy showed that periconceptional use of 800 µg folic acid in a multivitamin/multimineral preparation significantly reduced these defects (Ref. 30). Under current regulations, products with these dosages are drugs.

Based on a synthesis of information from several studies, including those that recorded use of multivitamins containing folic acid at varying doses, the PHS inferred that folic acid at levels of 0.4 mg per day will reduce the risk of neural tube defects (Ref. 1). This level is currently regulated as a food.

Whether other vitamins have an impact on the effect of folic acid when taken at low doses is not known. For example, Smithells et al. (Ref. 8) used 360 µg folic acid with other vitamins, and the Hungarian study (Refs. 27 and 30) used a dose of 800 µg folic acid with other vitamins. The study of Milunsky et al. (1989) (Ref. 13) examined folic acid as a component of multivitamins, and Mulinare et al. (1988) (Ref. 12) studied vitamin use but there was no documentation of folic acid use. All preparations associated with reductions in risk of neural tube defects, with the exception of preparations used in the Medical Research Council trial, contained (at least) vitamin A, vitamin D, thiamin, riboflavin, pyridoxine, vitamin C, and niacin in addition to folic acid. The results of Mills et al. (1989) (Ref. 10) showed no effect of folic acid from multivitamins or fortified cereals at a level of 400 µg. Information from a recent case-control study in Boston, Philadelphia, and Toronto suggested that a daily intake of 300 to 400 µg/day of folates from conventional foods offered significant protection from risk of neural tube defects (Ref. 31). The interrelation between several vitamins and folic acid may be explored by the advisory committee.

The difficulties in identifying a minimal potentially protective intake of folic acid are related in part to observations that poor folic acid status per se is not directly related to neural tube defects (that is, a dietary insufficiency of folic acid has not been consistently associated with increased risk of neural tube defects or predictive of women who would be most likely to benefit from folic acid supplementation). Neural tube birth defects are not among adverse pregnancy outcomes that have been associated with clinical folate deficiency in humans. Inconsistent results have been obtained in clinical studies carried out to determine if mild to moderate folate deficiency is associated with adverse pregnancy outcomes (Ref. 28).

For example, Yates et al. (1987) (Ref. 16) reported that although erythrocyte folate levels were lower in women who had several infants with neural tube defects, there was no association between erythrocyte folate levels and dietary folate intake. Thus, the risk for recurrence of a neural tube defect pregnancy could not be attributed to lower dietary folate intakes by mothers of affected infants (Ref. 16). Mills et al. (1992) (Ref. 37) recently measured levels of folate, vitamin B_{12}, and retinol in maternal serum samples drawn early in 89 pregnancies resulting in neural tube defect offspring and in 178 control pregnancies. Samples were obtained within 8 weeks of neural tube closure. The results of this population-based study in Finland, a low prevalence area for neural tube defects, demonstrated no relationship between maternal serum folate, vitamin B_{12}, and retinol during pregnancy and the risk of neural tube defects.

Nutrition during early pregnancy is critical for normal embryonic development. Human intervention and observational studies have focused on the periconceptional interval as a time when maternal nutritional status is particularly important, and when intervention may be of greatest value. In human embryogenesis, the neural tube forms and closes within the first month of pregnancy, often before a women realizes that she is pregnant.

5. Options for implementation

The supplementary information accompanying the PHS recommendation stated that there are three potential approaches for the delivery of folic acid to the general population in the dosage recommended. These include: (1) Improvement of dietary habits, (2) fortification of the U.S. food supply, and (3) use of dietary supplements. Each option has certain advantages and disadvantages. A careful review of these options is warranted as the agency works toward deciding whether and how to authorize a health claim.

V. Role of the Advisory Committee

Given the significance of neural tube defects and the recommendation of the PHS, FDA convened an advisory committee to help resolve the outstanding concerns on the effects of food claims describing the effects of folic acid intake on neural tube defects. The process that the agency has instituted and the concerns that need to be addressed and resolved are described below.

In addition to convening the advisory committee, the agency will conduct an indepth analysis of consumption patterns for specific foods across all age groups and both genders. The agency will consider various possibilities for fortification of foods, and such analysis will facilitate a determination of the effects of fortification of specific foods on overall intake in selected groups in the population.

The advisory committee heard testimony from experts as well as from other interested parties and provided recommendations to the agency on four broad issues:

(1) What is the target population that needs to be reached regarding the effects of folic acid on neural tube defects?

(2) How does the available information on the effective level of intake affect options for implemenation?

(3) What are the safety concerns for persons in the target population and in the general population?

(4) If a claim is to be authorized, what is the most appropriate method for presenting it to the target population?

An announcement of the meeting of the advisory committee and an opportunity to participate was provided in a Federal Register notice (57 FR 52781, November 5, 1992). The agency is reviewing the recommendations provided by the advisory committee.

VI. Impact Statements

A. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $108 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was

published in the **Federal Register** of November 27, 1991 (56 FR 60856). The agency requested comments on the RIA along with the food labeling proposals.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

B. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.71 is amended by adding new paragraph (c) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(c) Folic acid and neural tube defects.

Dated: December 17, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following table will not appear in the annual Code of Federal Regulations.

BILLING CODE 4160-01-F

Table. Estimates of intakes resulting from fortification of foods with folic acid

Folate/folic acid source	Amount (µg)	Estimate of bio-availability[1] (percent)	Free folic acid equivalent (µg)
Estimate A:			
Usual diet	300	50	150
Add foods fortified to unit limit of 400 µg:			
Plus 1 supplement	400	100	400
Plus 5 servings breads and cereals	2,000	75	1,500
Plus 2 servings fruit juice	800	75	600
Plus 3 servings dairy products	1,200	75	900
Total µg/day	4,700		3,550
Estimate B:			
Usual diet	300	50	150
Add foods fortified to unit limit of 400 µg:			
Plus 2 supplements	800	100	800
Plus 10 servings breads and cereals	4,000	75	3,000
Plus 4 servings fruit juice	1,600	75	1,200
Plus 6 servings dairy products	2,400	75	1,800
Total µg/day	9,100		6,950

[1]Estimates of bioavailability used in FDA's calculation were 50 percent for food folates, 75 percent for folic acid added to foods, and 100 percent for folic acid in supplements.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

21 CFR Part 101

[Docket No. 91N–0101]

RIN 0905–AB67

Food Labeling: Health Claims and Label Statements: Antioxidant Vitamins and Cancer

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision not to authorize the use on the label or labeling of foods of health claims relating to an association between antioxidant vitamins and cancer. However, FDA is authorizing a health claim relating substances in diets low in fat and high in fruits and vegetables (foods that are low in fat and may contain dietary fiber, vitamin A, and vitamin C) to a reduced risk of cancer. This action is in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims, and was developed in accordance with the final rule on general requirements for health claims, published elsewhere in this issue of the **Federal Register**.

Based on the totality of the publicly available scientific evidence, including recently available evidence, the agency has concluded that there is not significant scientific agreement among qualified experts that a claim relating antioxidant vitamins to reduced risk of cancer is supported. The publicly available evidence does indicate, however, that diets rich in fruits and vegetables, which are generally low in fat and high in vitamin A (as beta-carotene), vitamin C, and dietary fiber, are associated with decreased risk of several types of cancer and there is significant scientific agreement that the evidence supports this association. The evidence is not sufficient to attribute the reduction in risk specifically to vitamin A (as beta-carotene), vitamin C, or vitamin E, alone or in combination, or to other components of these diets. In order to evaluate further the relationship between antioxidant vitamins and cancer, FDA is planning to convene an advisory committee to review the available data and recommend whether a health claim for specific antioxidant vitamins and cancer should be authorized.

EFFECTIVE DATE: May 8, 1993.

FOR FURTHER INFORMATION CONTACT: John N. Hathcock, Center for Food Safety and Applied Nutrition (HFS–465), Food and Drug Administration, 200 C St., SW., Washington, DC 20204, 301–344–6006.

SUPPLEMENTARY INFORMATION:

I. Background

In the **Federal Register** of November 27, 1991 (56 FR 60624), FDA proposed to deny the use on food labeling of health claims relating antioxidant vitamins (specifically, vitamin C, vitamin E, and beta-carotene) to the risk of cancer. The proposed rule was issued in response to provisions of the 1990 amendments that bear on health claims and in accordance with the proposed general requirements for health claims for food (56 FR 60537). As amended by the 1990 amendments (Pub. L.101–535), the Federal Food, Drug, and Cosmetic Act (the act) provides that a food is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition unless the claim is made in accordance with section 403(r)(3) or (r)(5)(D) of the act (21 U.S.C. 343(r)(3) or 343(r)(5)(D)).

Congress enacted the health claims provisions of the 1990 amendments to help U.S. consumers maintain good health through appropriate dietary patterns and to protect consumers from unfounded health claims. Section 3(b)(1)(A) of the 1990 amendments specifically requires the agency to determine whether claims respecting 10 nutrient-disease relationships meet the requirements of section 403(r)(3) or 403(r)(5)(D) of the act. The relationship between antioxidant vitamins and cancer is one of the claims required to be evaluated. In carrying out this inquiry, FDA chose for consideration three antioxidant vitamins: vitamin C, vitamin E, and beta-carotene. Vitamins C and E were chosen because they are vitamins that function as antioxidants. FDA chose beta-carotene because it is an antioxidant, and because it is a provitamin and an important source of dietary vitamin A activity. FDA did not choose preformed vitamin A (retinol or retinoic acid) because its biological functions are not through an antioxidant role, and because vitamin A cannot function in an antioxidant fashion similar to that of beta-carotene (carotenoids) and vitamins C and E. FDA extended consideration of this topic area to all sources of antioxidant vitamins, i.e., both conventional foods and dietary supplements (56 FR 60624 at 60625).

FDA published a notice, in the **Federal Register** of March 28, 1991 (56 FR 12932), requesting scientific data and information on the 10 specific health claim topic areas identified in the 1990 amendments, including antioxidant vitamins and cancer. Relevant scientific studies and data received in response to this request were considered as part of the agency's review of the scientific literature on antioxidant vitamins and cancer in the proposed rule. Comments received in response to the notice and not specifically addressed in the proposed rule are summarized and addressed below.

In the proposed rule (56 FR 60624), FDA requested written comments on its tentative determination not to authorize a health claim for antioxidant vitamins and cancer. The agency specifically requested submission of data which directly bear on: (1) whether beta-carotene, vitamin C, and vitamin E per se, rather than some other component of food, decrease the risk of cancer in humans, and (2) the range of beta-carotene, vitamin C, and vitamin E intake that produce this effect. In addition, on January 30 and 31, 1992, FDA held public hearings on all aspects of the proposed rules published in response to the 1990 amendments (57 FR 239, January 3, 1992).

In the **Federal Register** of July 23, 1992, FDA published a notice reopening the comment period for three specific health claim topics, including antioxidant vitamins and cancer (57 FR 32751). In that document, FDA noted that the agency had received or identified several new studies on the relationship between antioxidant vitamins and cancer, which appeared to present significant new information that was not identified in the studies that FDA reviewed in its proposal. FDA listed the new studies and requested comments on them. Using the same criteria as described in the proposed rule (56 FR 60624 at 60629), these new studies are reviewed below. Comments received on the new studies are incorporated into the discussion of comments that follows.

Altogether, the agency received approximately 100 comments from consumers, consumer advocacy groups, State health departments, organizations of health professionals, the food industry, and Government agencies. A number of comments were received that were more appropriately answered in other companion food labeling documents, and these were forwarded to the appropriate docket for response.

The Dietary Supplement Act of 1992 (H.R. 6181) established a moratorium on the implementation of the 1990 amendments with respect to dietary supplements. The Dietary Supplement

Act says that FDA can grant health claims for foods, including dietary supplements, under section 403(r)(3)(B)(i) of the act. However, it may not act on such claims under section 403(r)(5)(D) of the act until it establishes a standard to implement that section of the act, which the Dietary Supplement Act says may not occur until December 1993. Section 3(b)(1)(A)(x) of the 1990 amendments directs the agency to evaluate the antioxidant vitamins and cancer claim based on the standard that FDA is establishing for determining the reliability of health claims under section 403(r)(5)(D) of the act. In the November 27, 1991, proposal on general requirements for health claims, FDA proposed to adopt the standard that the 1990 amendments provide for conventional foods, which is set forth in section 403(r)(3)(B)(i) of the act, as the standard for dietary supplements. Given this fact, and the fact that antioxidant vitamins are found in numerous conventional foods as well as in dietary supplements, FDA broadened its inquiry to a determination as to whether it should grant a health claim on antioxidant vitamins and cancer for any foods.

Because the Dietary Supplement Act provides that FDA may grant claims using the significant scientific agreement standard specified in section 403(r)(3)(B)(i) of the act, and given the breadth of FDA's November 1991 proposal on antioxidant vitamins, FDA has decided to move forward to determine whether it can authorize a claim under section 403(r)(3)(B)(i) of the act for antioxidant vitamins and cancer. However, this rule does not apply to dietary supplements. While a manufacturer of a dietary supplement can make a claim on antioxidant vitamins and cancer without rendering its product misbranded under section 403(r)(1)(B) of the act, the manufacturer should assure itself that the making of the claim will not misbrand the product under section 403(a).

II. Review of New Scientific Evidence: Beta-carotene, Vitamin C, and Vitamin E (Review of the Scientific Literature Available From 1991 Through February 1992, and Publications Submitted as Part of Comments)

A. New Studies

As noted in the **Federal Register** of July 23, 1992, results of several human studies have been reported in the scientific literature on the association between antioxidant vitamin intake and risk of cancer since the drafting of the proposed rule. Additionally, comments received in response to the proposed rule (56 FR 60624) noted some studies that FDA had overlooked in its proposal. FDA also identified some new studies through literature searches. Most of the new studies evaluated the effects of antioxidant vitamins in the larger context of diet and cancer, with some focusing primarily on the relationship of the antioxidant vitamins to fat and energy intakes. The recently available studies collectively addressed the relationship between antioxidant vitamins and a variety of types of cancer, including cancer of the breast, prostate, pancreas, uterine cervix, urinary bladder, colo-rectum, lung, and stomach.

Those studies submitted as comments which contributed to the totality of the scientific evidence on antioxidant vitamins and cancer are included in the following review. Those studies submitted as comments which were not germane to the topic or did not provide useful scientific information are addressed in the response to comments later in this final rule.

1. Overall cancer mortality rate

The relationship between vitamin C intake and total and cancer-related mortality rates in the United States was investigated through evaluation of the data from the National Health and Nutrition Examination Survey (NHANES I) (Ref. 1) (Table 1). The results indicated that higher vitamin C intakes are not significantly related to lower cancer mortality rates. The standardized mortality rate from all types of cancer collectively was a nonsignificant 0.78 for those taking supplemental vitamin C, compared with those who did not supplement with vitamin C.

2. Bladder cancer

A study of bladder cancer (Ref. 2) found that higher calculated vitamin E intake from foods was associated with slightly reduced risk of bladder cancer, after adjusting for smoking and total calories (Table 1). No association with cancer risk for the level of retinol or carotenoid intake was evident in this study. The participation rate was approximately 70 percent for the cases, the hospital-based controls, and the population-based controls. This study may have introduced bias by including prevalent cases (approximately 40 percent). Case-control studies usually select incident (newly diagnosed) cases. Prevalent cases are patients who have survived the disease for a period of time. Prevalent cases are generally not included in case control studies because the characteristics that contributed to their survival may modify potential risk factors of disease.

3. Breast cancer

In a recent study on breast cancer and foods that contain antioxidant vitamins (Ref. 3), dietary carotene and vitamin C intakes from foods were found to be associated with protection, but use of these constituents as dietary supplements had no effect on risk of breast cancer (Table 1). Patients with breast cancer tended to eat fewer than 10 fruits and vegetables per week. There was a low participation rate (56 percent of eligible cases and 46 percent of eligible controls), which may have introduced bias into the study. It is unclear why a large percentage of those identified as eligible did not participate, and this makes extrapolation of the results to the general population more difficult.

Another case-control study of breast cancer (Ref. 4) reported a marginal protective association between fruits rich in beta carotene and risk of breast cancer when premenopausal and postmenopausal women were evaluated together (Table 1). There was also a marginal protective association found for calculated preformed vitamin A (i.e., retinol) intake in postmenopausal women. When both premenopausal and postmenopausal women were analyzed together, the study found no significant association between antioxidant vitamin intake and the risk of breast cancer. There was also no evidence in this study that vegetable consumption was associated with reduced risk of breast cancer.

A case-control study in France (Ref. 5) found significantly higher intake and higher serum levels of vitamin E and higher serum vitamin E/total cholesterol ratio in breast cancer cases than in controls (Table 1). This effect remained after eliminating vitamin supplement users. Leukocyte vitamin E was elevated in cases; leukocyte vitamin C was also elevated in cases, but the elevation was not statistically significant. The report hypothesized that this effect may be the result of vitamin E-related metabolic alterations from breast cancer, rather than a cause of the disease.

Another case-control study on breast cancer (Ref. 6) found that diet was a more important risk factor for breast cancer in postmenopausal women than in premenopausal women (Table 1). After adjusting for energy intake, education, and age at menarche, the studies found that the intakes of dietary vitamin C, beta-carotene, total retinol equivalents and cellulose were positively associated with reduced risk of breast cancer in postmenopausal

women. The findings demonstrated that there was a marginally higher risk of breast cancer associated with high intake of nutrients from animal products and, after adjusting for the confounders described above, a lower risk associated with high intake of fruits and vegetables.

4. Cervical cancer

A recent case-control study of invasive cervical cancer (Ref. 7) reported that a slightly lower risk was associated with higher consumption of fruits and fruit juices (Table 1). No significant difference in risk of invasive cervical cancer was evident based on level of consumption of vegetables or legumes. There was decreased risk associated with higher intakes of vitamin C, beta-carotene, and other carotenoids. When vitamin C and beta-carotene were included in the same statistical model, the association for beta-carotene was attenuated, but the protective effect of vitamin C remained significant. This suggested that while beta-carotene and vitamin C are often present simultaneously in foods, the observed effect was more closely associated with vitamin C than beta-carotene. These results are difficult to interpret because there is generally more measurement error for beta-carotene intake than for vitamin C intake, and the strength of correlations may be affected by the size of the error variance.

A companion study in the same population (Ref. 8) focusing on serologic indicators of antioxidant vitamin intake found that intake of vitamin A (i.e., retinol), cryptoxanthin, lycopene, alpha-carotene, lutein, and vitamin E (alpha-tocopherol) did not significantly differ between cases of invasive cervical cancer and controls (Table 1). In addition, beta-carotene levels remained steady as cervical cancer progressed, arguing against an effect of disease progression on serum level. After adjusting for age, study site, reproductive history, socioeconomic status, and papilloma virus infection, higher serum beta-carotene and gamma-tocopherol levels were associated with decreasing risk of the disease. Considered together, the two studies found an association between beta-carotene intake, serum levels of beta-carotene, and decreasing risk of cervical cancer. In general, the protective effects were stronger for foods than for specific nutrients.

A clinical survey of patients with abnormal cervical cell types (cervicitis or dysplasia) in a recent study (Ref. 9) involved only 75 women and was confounded by smoking habits (Table 1). It did not have sufficient statistical power to find a significant difference in risk in relation to serum levels of antioxidant vitamins.

A case-control study of cervical intra-epithelial neoplasia in relation to dietary and serum carotenoids found ambiguous results for beta-carotene (Table 1) (Ref. 118). Protective associations were observed, however, for serum concentrations of the carotenoid lycopene and for dietary vitamin C.

5. Colorectal cancer

A study from the Balleric islands (Ref. 10) found no significant association between the risk of either colon or rectal cancer and the level of intake for vitamin A, retinol, carotene, vitamin C, or vitamin E (Table 1). There was a significant protective association for consumption of fiber from legumes and folic acid from cruciferous vegetables and reduced risk of cancer. The report stated that the findings support the recommendation for a diet high in vegetables as part of a lifestyle to reduce the risk of colorectal cancer.

6. Lung cancer

One of the new papers is a report of the results of a prospective cohort study (Ref. 11) regarding dietary intake of antioxidant vitamins and the risk of lung cancer in Finnish men (Table 1). The study found a protective effect associated with intake of foods rich in vitamins A, E, and C on the risk of lung cancer in nonsmokers. There was a strong protective association observed in this Finnish study between margarine intake and the risk of lung cancer in both smokers and nonsmokers. The report hypothesized that this finding was due to an effect of the vitamin E in margarine, although the researchers could not rule out an anticarcinogenic effect of some other constituent of margarine. Similarly, there was a lower incidence of lung cancer associated with consumption of foods that contributed 80 percent of the vitamin C in the Finnish diet (fruits, potatoes, and vegetables). The study could not separate the role of these nutrients from that of the foods which contain them in this association of reduced risk of lung cancer with diet, and could not rule out anticarcinogenic effects of other, nonnutritive constituents of fruits and vegetables, such as terpenes, flavones, and phenols. Also, behaviors possibly associated with intake of antioxidant-rich foods, such as exercise, not smoking, and decreased fat intake, may reduce cancer risk. The report concluded that studies focused on dietary patterns, intake levels, and protection against lung cancer by other constituents of antioxidant-rich foods are needed. Because the dietary estimate was based only on intake in the year preceding entry into the 20-year study, the estimate of antioxidant vitamin intake may not accurately represent the actual intake during the study duration, since changes in diet and supplement use were likely over the 20 years of the study.

Another new case-control study evaluated diet during the year preceding diagnosis and serum vitamin concentrations at diagnosis with lung cancer (Ref. 12) (Table 1). The calculated mean dietary intakes of beta-carotene were 24 percent lower for lung cancer cases than for controls, and 10 percent for other epithelial cancer cases than for controls. Serum concentrations of beta-carotene, retinol, and vitamin E were lower in the cancer patients than in the controls by 58, 30, and 31 percent, respectively, for lung cancer, and 33, 11, and 14 percent, respectively, for other epithelial cancer cases. The odds ratios for intakes of fruits and vegetables were rather irregular, and the associated trends were weaker than the trends for beta-carotene. The time period addressed in the dietary recall was the year prior to diagnosis. By comparison, cases in a 2-year period following sampling or interview are often excluded from prospective studies to help reduce the chance that the effects are a result of the cancer. Thus, the design of this study could have introduced bias related to deaths from preexisting cancer.

7. Oral and pharyngeal cancer

A population-based case-control study evaluated diet and dietary supplement use in relation to oral and pharyngeal cancer (Ref. 13) (Table 1). The results show decreased risk in association with higher consumption of fruits and vegetables and dietary supplements. In this four-State study, use of supplements was associated with being female, white, more highly educated, having a lower body mass, being a resident of California, and consuming more fruits and vegetables. Users of supplements of individual vitamin types were at lower risk after controlling for effects of tobacco, alcohol, and other risk factors. After adjustment for use of other supplements, vitamin E supplementation was the only one that remained associated with reduced risk.

8. Pancreatic cancer

A study on pancreatic cancer (Ref. 14) found a protective association between intake of dietary vitamin C and risk of pancreatic cancer after adjusting for

smoking and total calories (Table 1). Weak protective effects were also associated with vitamin A (i.e., retinol) and fiber intake and risk of cancer. Pancreatic cancer is characterized by a very rapid clinical course and deterioration of the pancreas, so dietary interviews and histopathologic confirmation are often not feasible. The Zatonski study may have introduced bias by using surrogates for assessing dietary history in 71 percent of cases. Reliance on a surrogate adds to the difficulty of recall. The spouse was sought as the surrogate in this study, because spouses generally provide reasonable dietary histories. Radiographic diagnosis of pancreatic cancer was used in 57 percent of the cancer cases. In lieu of a histologic diagnosis, the possibility of inaccurate diagnosis cannot be dismissed. This is a flaw in the study because noncases may have been included in the case group, and the signs of pancreatic cancer could have been confused with those of cancers of the upper gastrointestinal tract.

Another study on pancreatic cancer (Ref. 15) reported a statistically significant protective effect of vegetable consumption on the risk of pancreatic cancer after adjusting for smoking and total calories (Table 1). Protective effects were also demonstrated for consumption of both fresh vegetables and cooked cruciferous vegetables. This study did not separate the role of the food versus nutrients in the noted protective effects. A large percentage of dietary interviews relied on a proxy or substitute, which may have introduced errors in the estimates of food consumption. Proxies may not be aware of the complete dietary habits of the case that they represent.

9. Prostatic cancer

A study in Madrid, Spain, found no association between dietary vitamin A or C intake and the risk of prostate cancer (Ref. 16) (Table 1). However, the report noted that the customary Mediterranean diet is rich in fruits and vegetables. Any protective effect may have been pervasive at all levels of intake observed.

A case-control study of men in Utah (Ref. 17) found only a slight protective association between vitamin A intake in older men and the risk of prostate cancer (Table 1). Beta carotene had a nonsignificant protective association for prostate cancer in men aged 45 to 67 years. Dietary fat in men aged 68 to 74 years was the strongest association between a dietary risk factor and prostate cancer.

10. Skin cancer

A nested case-control study of serum micronutrients and low incidence cancer in Finland found a large decrease in risk of melanoma in association with higher serum beta-carotene concentrations (Ref. 18) (Table 1). There was a significant association, also, between higher serum alpha-tocopherol concentrations and reduced risk of melanoma. However, the small size of the study and wide confidence intervals prevent drawing strong conclusions from this study.

11. Stomach cancer

A case-control study of stomach cancer in high- and low-risk areas of Germany found a significant strong protective association between vitamin C from fruits and vegetables (RR = 2.32 for the lowest against the highest quintile of calculated intake) and risk of stomach cancer (Ref. 19) (Table 1). The results also implicated local water supply and smoked meat as possible sources of carcinogens or their precursors.

It has been suggested that vitamin C may reduce the risk for some cancers, particularly stomach cancer, through an antioxidant role in which the vitamin blocks formation in the stomach of carcinogens such as nitrosamines (Refs. 20 and 21). Most nitrosamines are mutagenic and carcinogenic in test systems, and, thus, many studies of the possible role of vitamin C in reducing the risk of cancer have focused on nitrate, nitrite, nitrosamines, and mutagenicity. Hence, several recent studies were directed toward relationships between vitamin C and formation of N-nitroso compounds, or between N-nitroso compounds and stomach cancer or precancerous pathology of the stomach. Data from such studies could prove useful in determining the specificity of vitamin C in relation to reduced risk of stomach cancer.

A case-control study in Shanghai, China, found that urinary ascorbic acid was lower and urinary nitrate higher in patients with gastric cancer than in normal controls (Ref. 22) (Table 1). The urine was not mutagenic (Ames test) in controls but the urine of subjects with dysplasia was somewhat mutagenic and that from gastric cancer patients was highly mutagenic. Normal controls had low levels of N-nitroso compounds in gastric juice, compared with the higher levels in patients with chronic atrophic gastritis, dysplasia or gastric cancer. The mutagenicity of the urine may have been related to synthesis of N-nitroso compounds in the stomach, and differences in this process may have been due to differences of ascorbic acid and nitrate. From studies of gastric cancer patients, without any other type of data, it is not clear whether the N-nitroso compounds are causal, predictive, or the result of gastric cancer.

The role of mutagenic/carcinogenic N-nitrosamides in stomach cancer was evaluated in a study with a complex, integrated design in China (Ref. 23) (Table 1). The study included: (1) Measures of mutagenicity of extract of local fish sauce before and after nitrosation, (2) determination of the carcinogenicity of these nitrosated products in the growing rat, (3) assaying the N-nitrosamides in these products, and (4) correlation of N-nitrosamides in gastric juice with the severity of precarcinogenic pathological changes in the stomachs of human subjects. In the absence of nitrosation, none of the fish sauce extracts was mutagenic. After nitrosation, all samples were mutagenic in common mutagenicity tests (Ames and sister chromatid exchange tests). The local fish sauce extracts from only two villages were mutagenic in the micronucleus test. Four weeks after treating newborn rats with fish sauce, only those treated with the sauce that was mutagenic in all three tests showed marked precancerous dysplasia. After 16 weeks, the same treatment groups had cancerous ulceration in the glandular stomach, with dysplastic glands and cells that had penetrated the mucosa and infiltrated into submucosa and muscular layers of the gastric wall. The mean concentrations of N-nitrosamides in the nitrosated fish products were more than 15 times higher in the samples from a high-risk area than in the samples from a low-risk area. The N-nitrosamide concentrations in gastric juice of human subjects had a strong positive correlation with the severity of pathological changes in the stomach.

A preliminary study in China (Ref. 24) found that N-nitroso compounds in the urine were higher in subjects with gastric dysplasia than in normal controls or subjects with chronic atrophic gastritis and/or intestinal-type metaplasia of the stomach (Table 1). The levels of N-nitroso compounds were lower in gastric juice than in the urine. With the small size and variability of this study, the N-nitroso compound levels in gastric juice could not be evaluated in relation to severity of stomach pathology.

The urinary concentrations of N-nitroso compounds and nitrate in urine of children from areas of low- and high-risk of stomach cancer in Costa Rica

have been studied (Ref. 25) (Table 1). The children were dosed with either 500 milligrams (mg) proline plus 200 mg ascorbic acid or 500 mg proline alone. (The proline was administered to assure that the quantities of N-nitrosoproline excreted were large enough to be chemically assayed in the 24-hour urine collected.) The amounts of N-nitrosoproline excreted were lower in the children from the low-risk area than from the high-risk area. In children from both areas, ascorbic acid treatment decreased the amount of N-nitroso-proline excreted. The N-nitrosoproline excretion had a highly significant positive correlation with the amount of nitrate excreted.

In a clinical trial involving English patients at high risk of stomach cancer (in this study, patients with atrophic gastritis, pernicious anemia, partial gastrectomy, or vagotomy), high doses of ascorbic acid (4 grams per day (g/day)) substantially decreased urinary N-nitroso compound excretion by all patients except those with pernicious anemia (Ref. 26) (Table 1). All patients received their normal diets, but avoided vegetable and fruit juices during the 4 weeks of the ascorbic acid treatment and 4 weeks of post-treatment observation. Serum ascorbic acid levels indicated excellent compliance with the ascorbic acid treatment.

A clinical trial of nitrosation of added L-proline by a high level of endogenous nitrate in test meals that were either low or high in endogenous ascorbic acid found that dietary levels of ascorbic acid significantly inhibit nitrosation of proline by dietary nitrate (Ref. 27) (Table 1). The results indicate that not all subjects synthesized nitrosoproline in vivo, and those who did not were the subjects who failed to show inhibition by ascorbic acid. Those who had in vivo nitrosation (13 of 19 subjects) showed strong inhibition of this process by ascorbic acid.

These results are supported by the results of a study that found lower excretion of nitrosoproline in subjects eating a lacto-vegetarian diet than in subjects eating a free-choice diet (Ref. 28). Supplementation with as little as 60 mg/day ascorbic acid decreased nitrosoproline excretion by the lacto-vegetarians, but not by those eating free choice diets. Supplementation with ascorbic acid at 300 or 3,000 mg/day decreased nitrosoproline excretion by both groups. Similarly, an earlier study found that dietary ascorbic acid (330 mg/day, principally from lemon juice) strongly decreased urinary excretion of two nitrosated products of the anthelmintic drug piperazine that are potent carcinogens in animals (Ref. 29). The inhibition of nitrosation by supplemental ascorbic acid decreases the mutagenicity of gastric juice (Ref. 30) and fecal mutagenicity (Refs. 31 and 32). Also, low concentrations of ascorbic acid in gastric juice are associated with chronic atrophic gastritis (Ref. 33) (Table 1), a condition widely considered to be premalignant (Ref. 34).

B. Conclusions From New Studies

1. Beta-carotene

Consistent with earlier studies reviewed in the proposed rule, these recent studies support findings that there is an inverse relationship between dietary intakes of green and yellow fruits and vegetables and the risk of cancer. This relationship is strongest for lung cancer. Intakes of the green and yellow fruits and vegetables have also been shown to be inversely associated with cervical cancer, but the evidence is not as consistent as with lung cancer. These studies were based on calculated intakes of nutrients from these foods. However, it is not possible to determine from these studies what substance or substances in these foods were responsible for the results. Beta-carotene may be responsible for the effect, or its presence in these foods may simply serve as a marker for some other unmeasured substances that are responsible for the protective effect of fruits and vegetables. Mechanistic studies provide a theoretical basis (singlet oxygen quenching) on which to postulate a protective antioxidant effect by beta-carotene, but the evidence from experimental animal carcinogenesis studies is less supportive. The evidence continues to be consistent with the conclusions of the major authoritative documents (e.g., "The Surgeon General's Report on Nutrition and Health" (Ref. 35) (the Surgeon General's report); the National Research Council's (NRC's) Report on Diet and Health: Implications for Reducing Chronic Disease Risk (Ref. 36) (the Diet and Health report); and the recent Life Sciences Research Office (LSRO) review (Ref. 37)) that the consumption of fruits and vegetables is inversely associated with risk of some cancers.

2. Vitamin C

Current data are compatible with the tentative conclusion in the proposed rule that consumption of fruits and vegetables rich in vitamin C may protect against some types of cancer. These data also provide additional indications of a mechanism to explain the relationship between vitamin C and reduced risk of stomach cancer. The relatively small number of studies reported since publication of the proposed rule are in agreement with earlier findings that consumption of fruits and vegetables is protective against cancer at several sites, particularly stomach cancer. The new studies, taken together with previous studies, indicate that consumption of fruits and vegetables is most consistently protective against cancers of the stomach, lung, and cervix, and less consistently protective at other sites. These data, however, are not sufficient to identify vitamin C versus other substances in these foods as being responsible for the observed protective effect.

The evidence from studies related to N-nitroso compounds is useful in identifying a mechanism, in human populations, whereby vitamin C could be responsible for decreasing the risk of some cancers, such as stomach cancer. The production of N-nitroso compounds with known carcinogenicity potential has been suggested as a cause of at least some stomach cancers in high-risk populations in China, Costa Rica, and Great Britain. The relevant data come from clinical trials showing the inhibition of nitrosation reactions in the stomachs of study populations, and epidemiological studies showing an association of N-nitroso compounds with precancerous and cancerous pathology of the stomach.

The results of the clinical trials on N-nitroso compound excretion, including new studies, indicate that levels of ascorbic acid from foods inhibit nitrosation reactions in humans by nitrite produced from dietary levels of nitrate, and that supplemental ascorbic acid within the range commonly obtained from foods (60 to 300 mg) can significantly decrease excretion of nitrosated products. Other new evidence shows that gastric juice and urinary nitrosamine concentrations are higher in normal persons in high-risk geographical areas than in normal persons living in low-risk areas, higher in persons with the more severe preneoplastic pathological changes in the stomach than in persons with less severe pathological changes, and higher in stomach cancer patients than in normal individuals. Ascorbic acid is only one determinant of endogenous nitrosation; dietary nitrate and its subsequent reduction to the nitrosating product nitrite by oral and gastric bacteria is also a strong determinant of endogenous nitrosation. Other determinants include nondietary influences such as smoking.

The carcinogenicity of N-nitroso compounds formed by endogenous nitrosation is determined by the amount of products formed and by their

chemical identities. The amounts formed are controlled by nitrate intake, nitrate reduction to nitrite, amounts of precursor amines available, and inhibition by ascorbic acid and other inhibitors of nitrosation. The identities of nitrosation products are determined by the identities of the precursor amines, available endogenously, in foods, or from other sources such as pharmaceutical products.

Although most of the several hundred nitrosamines and nitrosamides that have been tested are animal carcinogens, those used in evaluation of the potential for nitrosation in human subjects were selected because they are noncarcinogenic. Nevertheless, they provide a useful indicator of the effectiveness of vitamin C in decreasing the synthesis of carcinogenic members of the N-nitroso family of compounds. Studies of N-nitrosoproline, for example, must therefore be interpreted as indicators of nitrosation potential and associated risk of cancer, and not direct indicators of carcinogenic risk from that substance. It seems probable that the identities of precursor amines, and therefore of the N-nitroso compounds produced by endogenous nitrosation, will be different from one human population to another, depending on diet and other factors. Current scientific information is not sufficient to determine which specific mutagenic and carcinogenic N-nitroso compounds may be responsible for stomach cancer in various human populations, and it is reasonable to expect that these may vary from one population to another. Nonetheless, vitamin C is an inhibitor of the nitrosation reaction through its interaction with nitrite, regardless of the identify of the amine or amide being nitrosated and the corresponding identity of the resulting nitrosamine or nitrosamide.

The possible relationship of urinary and gastric juice N-nitroso compounds with stomach cancer is shown by the association of these compounds with precancerous pathological changes in the stomach and by the association of these pathologies with elevated risk of stomach cancer. The concentrations of N-nitroso compounds in gastric juice and urine are directly correlated with the degree of severity of the precancerous lesions in the stomach. The mutagenicity and carcinogenicity in test systems and experimental animals of N-nitroso compounds from food sources provide suggest a cause-and-effect relationship of N-nitroso compounds and stomach cancer in humans.

These effects cannot be interpreted as indicating that all stomach cancers are attributable to N-nitroso compounds or any other chemical carcinogens, or that vitamin C or other antioxidants can eliminate the risk of stomach cancer. Current data do not allow the exclusion of other mechanisms, such as general antioxidant effects, from the possible protective effects of vitamin C. Furthermore, the data from clinical trials showing inhibition of nitrosation reactions in the stomach, and epidemiological studies showing an association of N-nitroso compounds with precancerous and cancerous pathology of the stomach do not directly link vitamin C intakes with cancer risk or establish the validity of nitrosation reactions as a risk factor for stomach cancer in the U.S. population. These data provide a mechanistic basis for understanding a possible protective effect of vitamin C for stomach cancer risk. At this time, however, nitrosation has not been accepted by the general scientific community as a validated risk factor for stomach cancer. One of the unresolved questions is whether studies of this mechanism from the Chinese and other populations, which differ from the U.S. population in genetic, dietary, and environmental risk factors, adequately explain the etiology of stomach cancer in the United States.

3. Summary of vitamin C and cancer risk

Results from the newer data are similar to results of studies reviewed in the proposed rule, which showed that diets high in fruits and vegetables were associated with a reduced risk of some cancers. Additionally, the new data on the relationship of vitamin C in inhibiting nitrosation reactions in the stomach, resulting in reduced production of N-nitroso compounds with known carcinogenicity, provide a basis for a mechanism by which vitamin C may reduce the risk of some cancers such as stomach cancer in some people. However, these studies were done in populations outside the United States, so their relevance to the pathology and etiology of the types of stomach cancer in the United States is controversial. Furthermore, nitrosation has not received acceptance by many experts as a valid and quantifiable risk factor or surrogate marker for stomach cancer risk. Its validity and utility as an endpoint for evaluating the effect of nutrients on stomach cancer risk, therefore, warrants further discussion.

4. Vitamin E

The latest available information since the publication of the proposed rule is not sufficient to reach a definite conclusion about an association between vitamin E intake and the risk of cancer. Some studies provide suggestive evidence of an association of lower plasma/serum concentrations and lower dietary intake of vitamin E with increased risk of cancer. Mechanistic and animal studies provide a theoretical basis on which to expect a protective effect, but human studies are inconsistent and do not provide a convincing pattern of support for that conclusion. Even if an effect of vitamin E were assumed, it would not be clear from current data which specific chemical of the tocopherol family was responsible for the observed effect.

III. Summary of Comments and The Agency's Responses

Several comments supported the proposed rule to disallow a claim for antioxidant vitamins and cancer, without giving a rationale. Others supported the proposed rule, indicating that a cause-and-effect relationship of lowered risk has been established for fruits and vegetables, but that it is not clear that this relationship is due to the antioxidant vitamins in those foods.

The three final LSRO reports (Refs. 37 through 39) submitted as comments, which provided independent up-to-date reviews of the scientific evidence, also reached similar conclusions, except for vitamin C and stomach cancer. The LSRO report on vitamin C and cancer (Ref. 39) noted the consistency of epidemiological findings associating high intakes of vitamin C or vitamin C-rich foods with reduced risk of stomach cancer, but noted that vitamin C was either not related to other cancer sites or that study results were much less clear about such relationships. The LSRO report on Vitamin A and cancer (Ref. 37) concluded that, for foods containing beta-carotene, the associations with decreased cancer risk could not be attributed specifically to beta-carotene or to any other carotene compound. The LSRO report on vitamin E and cancer (Ref. 38) concluded that there was not a clear association of decreased cancer risk with consumption of foods high in vitamin E, and the tentative associations observed could not be attributed to vitamin E rather than to some other component. The report further stated that studies on vitamin E with animals and in vitro test systems provide a theoretical basis on which reduced risk of cancer can be hypothesized.

Many comments opposed the proposal not to allow a health claim for antioxidant vitamins and cancer. Issues raised in these comments are discussed below.

A. Scientific Standard and its Application

In the proposed rule (55 FR 60624), FDA reviewed the evidence and conclusions reached in recent authoritative documents from the Federal Government and other sources. The agency updated the evidence reached in these documents by reviewing all human studies in the literature subsequent to these documents, and by contracting with the LSRO of the Federation of American Societies for Experimental Biology (FASEB) for an independent review. The agency considered the results of animal studies to the extent that they clarified human studies or suggested possible mechanisms of action. The agency evaluated the strengths and weaknesses of individual studies and then assessed the strength of the overall combined evidence, taking into account the strength of the association, the consistency of findings, specificity of the association, evidence for a biological mechanism, and presence or absence of a dose-response relationship.

1. A number of comments discussed the types and weighing of data used by FDA in reaching its tentative position. Several comments noted that the proposed rule repeatedly suggested that epidemiological data are not enough, and that complete clarity must await the completion of clinical trials. One comment stated that clinical trials should be undertaken only when feasible and likely to yield a definitive answer, and that this is not the case for antioxidant vitamins and cancer. Other comments stated a belief that FDA favored prospective over case-control studies because they are less subject to misclassification and recall bias. One of these comments argued that there are advantages to case-control studies in cancer research and that concurrent followup (prospective cohort) studies are too expensive and time-consuming to be done often. The comment further noted that followup studies usually cannot address interactions and confounding factors because the necessary information does not exist or because too few subjects develop the cancer of interest, and that the case-control study is uniquely well-suited to the study of cancer and other diseases of long duration. A comment stated that most epidemiological studies handle the issue of nutrient intake from dietary supplements in a manner that obscures their impact, that many studies have insufficient power for specific outcomes, and that many involve inadequate or inappropriate questionnaires. Another comment stated that the 1990 amendments do not set out a drug efficacy standard, but only require that there be significant scientific agreement that a claim is supported by the scientific evidence.

FDA disagrees that the proposed rule indicated that clinical trials are specifically required to support a health claim. FDA's proposed validity standards for health claims and conformance with these standards were discussed in the proposed rule on general requirements for health claims (56 FR 60537 at 60547 through 60549). In that document, FDA noted that, while intervention (i.e., clinical) studies are generally more reliable than observational studies for determining cause-and-effect relationships, the agency recognized that there are frequently reasons why the conduct of such studies is not feasible or ethical. FDA also noted that, in evaluating proposed claims, it would take into account the overall strengths and weaknesses of the available data, and that a combination of various types of studies can frequently compensate for deficiencies in individual studies and thus provide a stronger case to prove or disprove a hypothesis. Furthermore, regardless of the type study used (e.g., case-control versus prospective), study designs are most useful when they can determine whether or not an observed effect is due to the specific food component of interest.

In the proposed rule on health claims for antioxidant vitamins and cancer (56 FR 60624 at 60629 through 60630, 60633, 60636), FDA listed additional criteria used in evaluating the scientific evidence for each of the three antioxidant vitamins and risk of cancer. FDA again indicated that it assessed the weaknesses and strengths of individual studies; and then the agency assessed the strength of the overall evidence, taking into account the strength of the associations, the consistency of the findings, the specificity of the associations, the evidence for a biological mechanism, and the presence or absence of a dose-response relationship. FDA noted that the agency's tentative conclusions reflected the strength, consistency, and preponderance of the data as reported. FDA did not speculate about what the results of specific studies might have been if they had involved different designs, greater statistical power, or more specific questionnaires.

After reviewing the conclusions of the federal government and other authoritative reports and the updated literature review, FDA concluded that the evidence is strong that consumption of fruits and vegetables that are good sources of beta-carotene and vitamin C are associated with lowered risk of cancer at a number of sites (56 FR 60624 at 60631, 60635, and 60638). However, the agency tentatively concluded that the data were not sufficient to establish that these two vitamins themselves were responsible for this association. The agency also noted that it was aware of ongoing clinical trials that, when completed, would provide valuable data about the specific effect of the antioxidant vitamins on the risk of cancer. However, the agency did not intend that this statement should be interpreted to mean that the results of these or other studies were a necessary condition for authorizing a health claim for the antioxidant vitamins and risk of cancer. Rather, the agency simply stated this information to indicate its awareness of these studies and the rapidly evolving nature of the scientific evidence relative to the topic area. While FDA discussed the relative advantages and disadvantages and generally agreed upon weighting of various types of human studies in a generic sense, the agency did not intend to convey the impression that one type of study would be rejected or that clinical studies were required. Rather, it was the overall sufficiency of the available evidence that was important.

FDA has not required a drug efficacy standard for health claims on foods under the 1990 amendments. The requirements for demonstration of drug efficacy differ substantially from the scientific standard for authorization of health claims on foods. For example, clinical trials are necessary to gain approval of a new drug; as discussed above, they are not required for authorization of a health claim on food, if other types of available data are sufficient.

2. A comment expressed concern that the agency had used a more liberal standard in evaluating health claims for calcium and osteoporosis and lipids and cancer than for antioxidant vitamins and cancer. The comment cited the proposed rule on dietary lipids and cancer (56 FR 60764 at 60765 through 60766, November 27, 1991) in which FDA quoted from the diet and health report that data from epidemiological and experimental animal studies were sufficient to support a claim that dietary fat may influence the risk of some types of cancer, although the precise determination of the quantitative relationship and nature of the association between dietary fat and the overall risk of cancer has not been determined. The comment compared the proposed rule on antioxidant vitamins and cancer (56 FR 60624 at

60631 through 60632), arguing that FDA concluded that similar data are inadequate to support a claim for antioxidant vitamins and cancer. The comment claimed that distinctions between the arguments FDA used to accept a claim on lipids and cancer and reject a claim on antioxidant vitamins and cancer are illusory at best.

FDA disagrees with the assertion that the agency applied a variable standard for authorizing various health claims. For some topics such as calcium and osteoporosis, sodium and hypertension, lipids and heart disease, and lipids and cancer, there was a long history of review by expert panels from the Federal Government, the National Academy of Sciences, and other authoritative groups. These groups concluded that the science supports these nutrient/disease relationships, and this fact provides evidence for significant scientific agreement among qualified experts about the state of the evidence. In contrast, the authoritative reviews have concluded that the publicly available data do not support a conclusion that the antioxidant vitamins reduce cancer risk. In reviewing the recent human studies which became available subsequent to publication of these authoritative reports, FDA did not find compelling evidence that these nutrients were specifically responsible for reduced risk of cancer in persons consuming diets high in fruits and vegetables. Without such data, FDA could find no basis to conclude, counter to these previous conclusions of expert panels that, based on the totality of evidence, there is significant scientific agreement that an antioxidant vitamins/cancer claim is supported.

3. Some comments stated that FDA has relied on the Surgeon General's report (Ref. 35) and the Diet and Health report (Ref. 36) without considering all recent publications. These comments noted that the earlier authoritative reviews failed to consider all of the available data, and thus some of their conclusions may have rested on incomplete data. The comment also noted that the explosion of new research on the relationship between antioxidant nutrients and cancer has produced a large number of recently published studies which escaped the LSRO reviews. The comment also identified a number of studies included in the LSRO reviews that were not included in the tables published in the proposed rulemaking. The comment suggested that, while this may or may not have influenced the decisionmaking in this case, it might provide an incomplete picture to others who read the FDA proposal.

FDA disagrees with these statements. FDA considered not only the Surgeon General's report (Ref. 35) and the Diet and Health report (Ref. 36), but also all available recent publications that were relevant to the issue, including the recent review by the LSRO (Refs. 37 through 39). FDA recognizes that the authoritative review documents may not have considered and certainly did not cite every available publication related to the subject matter under consideration. FDA believes, however, that they authoritatively considered the original research publications and critical reviews necessary to reach accurate conclusions about the state of the scientific evidence on antioxidant vitamins and cancer.

The topics in the authoritative reports were evaluated by nationally recognized experts who would be expected to be familiar with all significant findings available at the time of the reports. Furthermore, except for the LSRO reports, these reports were subject to no requirements to list, as references, all available scientific literature. Most likely, they followed the common procedure of the scientific community and listed only those studies considered most relevant to the issues under review. FDA advises that any papers which were not cited in these reports but which commenters felt were important could have been submitted as comments to the public docket. Those that were submitted were included in FDA's review of new studies, or if not appropriate for inclusion in that section, are discussed in specific comments.

FDA also acknowledges that not every paper cited in the LSRO reviews was incorporated into the proposed rule. Conclusions from the LSRO preliminary reports were considered in developing FDA's proposed rule. Those relevant studies not included by FDA in the proposed rule, but cited by LSRO, have been included as new scientific evidence in this final rule (see section II. of this document).

The additional studies cited by one comment either are not sufficiently relevant to warrant their inclusion in the review of new scientific evidence, did not meet the inclusion criteria in the proposed rule, or are old enough to have been considered for inclusion in the Surgeon General's report (Ref. 35) and the Diet and Health report (Ref. 36) or the recent reviews by the LSRO (Refs. 37 through 39). There is broadly based scientific agreement of an association between dietary patterns high in fruits and vegetables and reduced risk of cancer, as acknowledged in the proposed rule, and in the Surgeon General's report (Ref. 35) and the Diet and Health report (Ref. 36). However, studies that identify or confirm the established relationship of protective effects of fruits and vegetables on cancer risk without providing data on the unresolved question of the specificity of one or more of the antioxidant vitamins in relation to reduced risk of cancer are not helpful in supporting a health claim on antioxidant vitamins and cancer. Those studies that are newer and more nearly relevant to the issue of antioxidant vitamins and cancer, in contrast to fruits and vegetables, are summarized and cited in Table 2 (Refs. 41 through 59). One study described and listed in Table 2 (Ref. 46) is a further description of a study already reported elsewhere and considered in the proposed rule. Those listed by the comment but not included in the review of new scientific evidence in an earlier section of this document, and not cited in Table 2, were reviewed and found either to be not sufficiently relevant, to not have found significant results, or to be old enough to have been included in earlier reviews if that had been considered appropriate (Refs. 60 through 109).

4. Some comments argued that the biochemical data on the effects of antioxidant vitamins on the probable mechanisms of chemical carcinogenesis are strong evidence, and could stand alone in support of an association between antioxidant vitamins and cancer. One comment suggested that numerous studies have shown antitumorigenic effects of antioxidant vitamins in animal models, and, although not showing protective effects from every nutrient in every animal model and in every dosage regimen, quite consistently show a strong and significant protective effect. However, no data were submitted to support this assertion.

FDA disagrees with these comments. Although biochemical data can indicate the possibility of a protective effect of the antioxidant vitamins against cancer, they cannot demonstrate that the effect is one of practical importance in humans, in the context of the total daily diet, alone, support a health claim. FDA recognized in the proposed rule that animal and mechanistic data provide a strong theoretical basis on which to postulate that the antioxidant vitamins decrease the risk of cancer in humans. FDA does not agree, however, that such evidence alone are sufficient to support the conclusion that the effect is necessarily of practical importance in humans, in the context of the total daily diet.

5. Some comments stated that FDA's fragmented approach to considering the

evidence has made it difficult to see the extraordinary consistency of the data. These comments state that, although the 1990 amendments directed FDA to consider a health claim regarding "antioxidant vitamins and cancer," the agency chose to consider three antioxidants (beta-carotene, vitamin C, and vitamin E) separately. The comments stated that this approach is counter to the requirements of the 1990 amendments and is inherently incapable of revealing the consistency of the data on the antioxidant vitamins. A few comments stated that FDA should have reviewed selenium.

FDA disagrees with these comments. The term "antioxidant" defines a functional characteristic of a substance rather than its specific identity. Antioxidant nutrients include the vitamins under consideration and the mineral selenium. FDA has not considered selenium, because the 1990 amendments specified "antioxidant vitamins and cancer," and, although it is an antioxidant, selenium is not a vitamin.

FDA reasonably interpreted the language of the 1990 amendments to refer either to an independent effect of one or more of the vitamins with antioxidant characteristics (i.e., vitamins C and E, and the provitamin A, beta-carotene) or to an effect of a combination of two or more of the antioxidant vitamins. Certainly, FDA did not interpret the language of the act to mean that the only effect to be considered was that of the three antioxidant vitamins in combination. FDA recognizes that much of the data from surveys of dietary patterns and intakes of specific foods involve consumption of combinations of the antioxidant vitamins. The agency notes, however, that the composition of fruits and vegetables includes many substances other than the antioxidant vitamins, such as dietary fiber, and believes that the results of studies of fruit and vegetable intake cannot be interpreted as demonstrating that a combination of the antioxidant vitamins is responsible for the observed protective effects. FDA advises, however, that a petition in support of a health claim for a combined effect of the three antioxidant vitamins may be submitted for evaluation.

6. Some comments stated that, in the proposed rule on antioxidant vitamins and cancer, FDA made a "Type II error" by failing to identify an effect when it exists. (In contrast, a Type I error is that of mistakenly identifying an effect when it does not exist.) The comments indicated that this type of error causes important health benefits that are justified by the available evidence to be denied. These comments also stated that a benefit/risk analysis could properly be used to allow health claims because the agency had stated in the proposed rule that "FDA will use its discretion to give greater weight to those studies that are more persuasive regardless of the nature or age of the studies."

FDA agrees that both types of error are possible. In general, decreasing the probability of a Type II error will increase the probability of a Type I error, and vice versa. In the proposed rule on general requirements for health claims (56 FR 60537 at 60547), FDA noted that the standard for conventional foods in the 1990 amendments required that the agency have a "high level of comfort that the claim is valid." FDA proposed that the same standard be used for both conventional foods and dietary supplements (56 FR 60357 at 60547). FDA believes that it has properly balanced the probabilities of making the two types of error by requiring that the totality of the data support the disease/nutrient relationship. Giving more weight to studies that are most persuasive, within the broader context of the strengths and weaknesses of individual studies and the types of evidence available, is appropriate in assessing the totality of the evidence. This approach does not, however, permit selective use of studies supporting a relationship at the expense of evaluating those studies which fail to support the relationship. Moreover, FDA's cited statement in the proposal does not support use of risk/benefit analysis to evaluate a health claim. Such an analysis would be inappropriate. FDA is responsible for ensuring a safe food supply, and thus foods bearing health claims must be demonstrated to be safe and lawful. (See § 101.14(b)(3)(ii)).

7. A comment stated that, in proposing not to authorize health claims for antioxidant vitamins and cancer, FDA was inconsistent with its cosponsorship, with the American Health Foundation, of a recent international conference on antioxidants and cancer. The comment stated that the overall content of the conference was to substantiate the protective effect of antioxidant vitamins against cancer.

FDA agrees that research discussed in the conference provided further evidence of the existence of plausible and substantiated mechanisms, including inhibition of nitrosation reactions, inhibition of free radical oxidations, and support of immune responses, through which antioxidant vitamins may decrease the risk of cancer. FDA also agrees that the conference provided evidence of the association of consumption of foods that are good sources of beta-carotene and vitamin C with protection against certain cancers. The research presented at the conference was generally consistent with a protective relationship between antioxidant vitamins and cancer, but the conference organizers and participants did not directly address whether the evidence met the standards and criteria specified in the 1990 amendments.

B. Relationships Between Antioxidant Vitamins and Cancer

8. Some comments asserted that a major problem with the proposal is that all cancers are referred to together. They further stated that the 1990 amendments do not specify or define antioxidant vitamins, and this makes it impossible for a regulation to be issued.

FDA disagrees. In the proposed rule (56 FR 60624 at 60633 through 60636), FDA broke out its review of vitamin C by type of cancer. There were insufficient data on beta-carotene and vitamin E for such an organizational structure. FDA does not believe that the organization of its review biased the conclusions. However, in the scientific review for this final rule, FDA organized its review of the effect of antioxidant vitamins by type of cancer. FDA's approach was again driven by the availability of data. As explained in the proposed rule, FDA selected beta-carotene, vitamin C, and vitamin E for review because they are vitamins (or, in the case of beta-carotene, a provitamin), they have antioxidant properties, and their known biological functions are through antioxidant activities.

9. Some comments disagreed with the statement by FDA that the amount of antioxidant vitamins needed to produce an effect must be identified. A comment also objected to the agency's statement that it would need to determine whether the food supply already provides that amount of the antioxidant vitamin, arguing that this is not a valid requirement because it does not consider variations in dietary intake. This comment stated that: (1) If FDA needs to know simply that effective levels may be obtained in a normal diet, the epidemiology can tell us that, and (2) if FDA is attempting to identify a specific amount, then this quest is misguided for several reasons. The reasons given included: (1) The required level is determined in part by the level of oxidant stress, (2) most of the epidemiologic data suggest that there is not a threshold, but rather a continuous trend of decreasing risk with increasing intake, and (3) the effective level may

well differ for different cancer sites. The comment stated that: (1) Protective levels are in the range attainable in the context of the total daily diet, and (2) in contrast to FDA statements or implications in the proposed rule, the antioxidant nutrient status of the U.S. population is not ample. No definition was given, however, for "ample."

FDA agrees that, if a cause-and-effect relationship has been shown for a particular type of cancer and a specific antioxidant vitamin, epidemiological data can be relied upon to indicate effective levels. FDA disagrees that any attempt to identify precise amounts of the antioxidant vitamins needed to decrease risk of cancer is misguided. The agency acknowledges the important considerations raised by the comment, but considers the rationale incomplete. Amounts of specific vitamins must be identified to provide a regulatory basis for the qualifying criteria for a health claim. In the final rule on general requirements for health claims published elsewhere in this issue of the Federal Register, FDA has concluded that foods that bear a health claim must contain meaningful amounts of the targeted nutrient relative to the claimed effect (in this instance, potential for reduction in cancer risk) (§ 101.14 (21 CFR 101.14)). Any alternative approach would be misleading to the consumer.

FDA agrees, however, that, if the cause-and-effect relationship has been shown, protective levels might include the range most commonly obtained from the diet. Because protective levels of the antioxidant vitamins are not known, it seems futile to speculate as to whether protective levels, if and when identified, will be attainable within the context of the total daily diet. As is explained fully in the preamble of the final rule on the general requirements for health claims published elsewhere in this issue of the Federal Register, it would not be permissible for a health claim to imply that levels clearly beyond the range attainable in the context of the total daily diet would be effective in reducing the risk of a disease or health-related condition.

FDA acknowledges that its statements about the need for information on the current dietary status for the antioxidant vitamins in the proposed rule were not clear. The agency also agrees that high average intake and high intake in major population groups do not indicate that all individuals or population subgroups would have similarly high intakes. However, because of space limitations on food labels, it is not possible to provide information on the recommended nutrient intakes for major age and sex groupings or for all situations which might affect need. Rather, labels will show a reference value, and educational programs will help consumers understand the relevance of the reference value to their individual needs.

10. A comment stated that results from epidemiological studies are sufficient to show that the antioxidant vitamins per se decrease the risk of certain cancers. Some comments claimed that FDA's statement that the effects of fruits and vegetables cannot be specifically attributed to the antioxidant vitamins is not valid and is biased against dietary supplements in that the data on antioxidant vitamins and cancer are no more confounded than those on dietary fat and cancer. A comment stated that, although FDA documents note repeatedly that the evidence for fruits and vegetables is strong, FDA nevertheless rejected a health claim on the antioxidant vitamins and cancer on two grounds: (1) The association could be due to other factors associated with fruit/vegetable intake, and (2) even if the protective factor is an antioxidant, it is not clear which nutrient is effective. Several comments stated that FDA should allow a qualified claim such as "a diet high in fruits and vegetables containing antioxidant vitamins may help reduce the risk of certain cancers."

FDA agrees that the scientific evidence is strongly supportive that diets high in fruits and vegetables are associated with a reduced risk of several types of cancer. Theoretical considerations and some research findings have suggested that several common components of fruits and vegetables, or substances at low concentrations in diets containing large quantities of these plant foods, may be responsible for reduced risk of cancer, including vitamin C, beta-carotene, other carotenoids, vitamin E (alpha-tocopherol) or other tocopherols, dietary fiber, folic acid, and other substances such as the indoles in cruciferous vegetables. Fruits and vegetables may also provide a protective effect because they are generally low in fat and calories, and because they may displace higher fat foods in the total diet. In the final rule on general requirements for health claims (§ 101.14), FDA notes that labeling statements relating ingestion of general food groups (e.g., fruits and vegetables), in which a specific substance is not implied, to a disease or health-related condition will not be regulated as health claims under § 101.14, but will be subject to the requirement in section 403(a) of the act that they be truthful and not misleading.

FDA concludes that epidemiological studies of associations between food consumption and cancer, in which the antioxidant vitamins are provided almost entirely by fruits and vegetables, are not likely by themselves to establish a cause-and-effect relationship between antioxidant vitamins and cancer sufficiently to generate significant scientific agreement. It is not possible from these studies alone to identify the particular substances or combination of substances responsible for the effect. FDA recognizes that many studies have used multiple regression procedures to control for potential confounders and to attribute specificity to statistically significant relationships. However, unless all effective components are measured, it is not possible to differentiate between a measured variable which may be serving as a marker for other unmeasured components in the food and a real effect of the measured nutrient itself.

As to the concern expressed that FDA intentionally discriminated against dietary supplements, FDA disagrees. FDA, as stated in the proposed rule on general requirements for health claims (56 FR 60357), focused on the role of specific nutrients or foods as they relate to reduction in risk of a disease, regardless of source. The source of vitamin C, for example, could thus be naturally occurring vitamin C in foods, vitamin C added as a fortificant, or vitamin C obtained from dietary supplements. Consumers obtain their nutrients from a variety of sources. FDA's conclusions were driven by the nature of available evidence: for antioxidant vitamins and cancer, most of the available evidence is from studies on consumption of fruits and vegetables.

In regard to a health claim on conventional foods in which specific nutrients are named, such as "diets high in fruits and vegetables containing antioxidant vitamins may reduce the risk of cancer," FDA is persuaded by the comments that a similar claim may be useful, and that a similar claim is supported by the evidence. FDA, therefore, has decided to authorize a health claim relating low fat diets high in fruits and vegetables (which are low in fat and may contain vitamins A and C and dietary fiber) to a reduced risk of some types of cancer. Statements relating foods to cancer risk with acknowledgment of significant nutrient contributions of those foods to total diets are frequently the types of statements used in Federal Government and other dietary guidelines. The 1990 amendments clearly indicated that Congress intended that health claims on foods be a useful source of information to help Americans implement the U.S. Dietary Guidelines for Americans (Ref.

40). The authorized claim will provide such useful information.

11. One comment argued that time-release formulations of antioxidant vitamins are superior to standard formulations in their ability to decrease the risk of cancer, and that cancer clinics are using them successfully.

This comment did not provide scientific support for a conclusion that time-release formulations of the antioxidant vitamins have been shown to provide any special benefit or advantage over standard formulations. The literature submitted in support of the assertion consisted of general, nonscientific review and position statements, and was not useful in assessing the totality of the scientific evidence on the relationship between antioxidant vitamins and cancer. Moreover, FDA does not consider the issue of time-release formulation to be relevant to this rulemaking.

12. One comment submitted a copy of the entire April 1, 1992, issue of Cancer Research (Vol. 52, pp. 2091s through 2126s). Some comments submitted a review (Ref. 110) of carotenes, vitamin C, and vitamin E as protective antioxidants in human cancers.

One paper in the submitted issue of Cancer Research addressed antioxidant vitamins and cancer (Ref. 111) concluded that increased intakes of fruits, vegetables, and carotenoids, and elevated blood levels of beta-carotene are consistently associated with reduced risk of lung cancer. Nevertheless, this review concluded that, with current data, the effects of beta-carotene cannot be identified separately from those of other carotenoids, other constituents of fruits and vegetables, and associated dietary patterns.

The other review covered both animal experiments and epidemiologic research. Its overall conclusion was that antioxidant nutrients appear to play many important roles in protecting the body against cancer, but many important questions remain before dietary supplementation and/or food fortification can be recommended. In contrast, it concluded that there is a strong scientific basis for current dietary recommendations that emphasize frequent consumption of fruits and vegetables.

13. Another comment stated that the study on beneficial effects of dietary supplementation on longevity (Ref. 1) used inappropriate methods and therefore should not be used for identification of benefits from use of supplements. This comment stated that a major problem lies in the fact that cancers develop at different rates, thus requiring more time for conclusive studies.

FDA has indicated elsewhere in this document that this study did not find a significant effect of any antioxidant vitamin on cancer mortality. Thus, while the issue of the relevancy of the methods used may merit scientific review, it has no practical effect on the conclusions reached relative to health claims.

C. Safety Issues

14. Several comments disagreed with the statement by FDA in the proposed rule that high intakes of one vitamin without commensurate increases in the others may not support optimum status and functions for these nutrients. The comments stated that dietary supplements provide greater opportunity for deliberately balanced intakes of the antioxidant vitamins than do foods, and other comments asserted that FDA is wrong in stating that foods provide a better balance of antioxidant vitamins than do dietary supplements. The comments also suggested that interactions can be protective, as illustrated by data from animal experiments.

FDA agrees that dietary supplements allow the opportunity to provide a more controlled amount of nutrients than do foods. However, in the case of antioxidant vitamins and cancer, the scientific evidence from data that are customarily used in setting dietary goals and nutrition policy is not sufficient at present to identify an independent effect of these substances. Therefore, any attempt to define dosages or optimum balances among the three antioxidant vitamins is premature. The statement that foods may provide a better balance is consistent, therefore, with the limitation of current scientific evidence.

Additionally, FDA agrees with the statement that interactions can be either helpful or harmful. However, FDA's decision to propose not to authorize a health claim on antioxidant vitamins and cancer was not based on concern about toxicities or adverse interactions among nutrients, but, instead, on the insufficiency of the data available.

15. Some comments expressed concern that, if a health claim were permitted for vitamin C, the public might take supplemental doses far in excess of the Recommended Dietary Allowances, and that this could result in gastrointestinal disturbances, iron overload in some people, precipitation of calcium oxalate kidney stones, disruption of copper metabolism, and induction of postnatal bleeding in women. They also stated that dietary supplements should be required to list a warning statement regarding use of the supplement along with any health claim permitted.

FDA points out that most reports of possible adverse effects from ascorbic acid ingestion have involved dosages of 3 to 30 g per day (Ref. 112). The Surgeon General's report (Ref. 35) states that amounts of vitamin C in excess of the Recommended Dietary Allowance may cause rare adverse effects, but does not identify how far above the Recommended Dietary Allowance values adverse effects are observed. The adverse effects noted include gastrointestinal disturbances, iron overload in susceptible individuals, altered metabolism of certain drugs, precipitation of calcium oxalate kidney stones, altered absorption (both positive and negative) of several minerals, and interference with several laboratory tests. The review article cited as the source of this information (Ref. 112) concluded that, although the effects listed should be considered possible, consumption of supplemental vitamin C leads to no significant adverse health effects in humans in general, but nevertheless individuals who have a history of kidney stone formation and those who experience iron overload should exercise caution before using supplemental vitamin C.

The Diet and Health report (Ref. 36) recommends avoiding taking dietary supplements in excess of the Recommended Dietary Allowance in any one day. It states that several vitamins and minerals, if consumed in excess, can be toxic and cause numerous adverse health effects, but that there is no evidence that the public is harming itself by the use of low levels of supplements. This report did not discuss the possible adverse effects of vitamin C in detail, but instead reprinted a table from a review article in which the adult oral minimum toxic dose was estimated to be between 1 and 5 g. The NRC's "Recommended Dietary Allowances" 10th ed. (Ref. 113) stated that many persons habitually ingest 1 g. or more of ascorbic acid without developing apparent toxic manifestations, although a number of adverse effects have been reported.

Additionally, the LSRO report (Ref. 39) indicates that intakes of ascorbic acid of up to 1 g/day are well tolerated (Ref. 114). Occasionally, intakes above this may be associated with nausea and diarrhea. Ascorbic acid intakes of 4 g/day were used in a long-term intervention trial on rectal polyps without adverse effects in a population of adult men and women (Ref. 115).

FDA is not currently authorizing a health claim relating antioxidant vitamins and cancer. If such an authorization occurs in the future, these conclusions about vitamin C may be used in evaluation of its safety.

16. Some comments addressed the issue of possible iron overload as a result of high vitamin C intake. The comments stated that vitamin C added to foods can increase the amount of iron absorbed. These comments refer to a longstanding concern that persons carrying the genetic trait for idiopathic hemochromatosis, and perhaps also persons with the heterozygous trait, are at risk of earlier onset of the disease or more severe effects if the intake or bioavailability of dietary iron is increased. One comment, however, concluded that the effect, although likely to be insignificant in normal individuals, may be slightly greater in those who are heterozygous for the gene for hereditary hemochromatosis. This comment noted that an effect as great as doubling of iron stores might result, under very specific conditions of iron to ascorbic acid ratio in the food, from switching to a vitamin C-fortified food from a nonfortified food and continuing this practice for several years. Such a situation is presumably unlikely to occur frequently, making the potential impact on iron status much smaller.

FDA recognizes that the role of vitamin C in enhancing iron bioavailability under short-term test conditions is well established (Ref. 116). Studies in normal persons without the idiopathic hemochromatosis genetic trait show no increase in iron stores with chronic intakes of large amounts of supplemental ascorbic acid (Refs. 115 and 116). FDA, however, was not able to find similar studies in patients with hemochromatosis, and no such data were submitted as comments. Thus, the issue of safety of ascorbic acid intakes in enhancing iron uptake by hemochromatosis patients, and the dose-response relationship of ascorbic acid in this effect, cannot be resolved from current data.

17. A comment stated that FDA makes much of the need to determine precise intake levels of beta-carotene, vitamin C and vitamin E regarding potential benefits, but resorts to the broadest generalizations when it comes to possible detrimental actions of excessive intakes of vitamins. The comment pointed out that the amounts of vitamin C in diets recommended by the U.S. Department of Agriculture (USDA) and the National Cancer Institute exceed 200 mg, and that the situation is analogous for vitamin E.

FDA agrees that the proposed rule described the need to identify levels of antioxidant vitamins that are effective in reducing the risk of cancer, and that possibilities were discussed for adverse effects. The agency also is aware that current dietary patterns in the United States consistently result in average intake levels above current Recommended Dietary Allowances. The agency's discussions on effective intakes were presented because this issue can affect evaluations of safety. This information is also essential for determining qualifying criteria for foods bearing an authorized claim, and for deciding on the types of information needed to be included in a label statement. Estimates of current dietary intakes or intakes likely to occur if persons follow dietary guidelines are largely irrelevant to evaluating whether a nutrient/disease relationship exists.

IV. Decision Not to Authorize Health Claims Relating Antioxidant Vitamins and Cancer and to Authorize Health Claims Relating Substances in Fruits and Vegetables and Cancer

A. Scientific Evidence Regarding the Relationship between Antioxidant Vitamins and Cancer and Between Fruits and Vegetables and Cancer

FDA has reviewed numerous authoritative documents, including Federal Government reports, as well as recent research on diet and cancer risk. In addition, the agency considered all comments received in response to its proposed rule. The agency has concluded that the scientific evidence does not provide the basis for significant agreement among qualified experts that there is a relationship between antioxidant vitamins (specifically, beta-carotene, vitamin C and vitamin E) and a reduced risk of cancer. However, the publicly available scientific evidence does support an association between diets high in fruits and vegetables, which are good sources of two of the antioxidant vitamins (vitamin A as beta-carotene and vitamin C) and reduced risk of cancer.

Based on the scientific evidence in the proposed rule, the comments received, and new studies, FDA has reached the following decisions:

1. Vitamin E

Based on a review of the totality of the scientific evidence and comments received relative to the available evidence, FDA concludes that the data do not support a relationship of vitamin E to reduced risk of cancer and that there is not significant scientific agreement that vitamin E reduces the risk of cancer. Most studies on the possible protective effect of vitamin E have related plasma or serum levels of vitamin E (rather than fruit and vegetable consumption) to cancer risk. FDA recognizes that some evidence shows an association of low plasma/serum levels of vitamin E and reduced cancer risk, but finds that the inadequacies in the available data, as noted in the proposed rule (56 FR 60624), have not been adequately addressed by newer data; comments received in response to the proposed rule were not sufficiently convincing to reverse the proposed conclusion.

FDA recognizes that the animal and biochemical data provide a basis on which to hypothesize a protective effect by vitamin E (alpha-tocopherol) in humans, but the data from epidemiological studies, although providing some suggestion of an effect, are not sufficient to conclude that such effects are of importance in humans. Therefore, although vitamin E has been shown to have antioxidant effects in humans, the data are not sufficient to associate such effects with protection against cancer.

2. Beta-carotene

Based on a review of the totality of the scientific evidence and comments received relative to the available evidence, FDA concludes that data do not support the relationship of beta-carotene (provitamin A) to reduced cancer risk. FDA also concludes that there is not significant scientific agreement that beta-carotene reduces the risk of cancer. However, the available data show an association of consumption of fruits and vegetables and calculated beta-carotene intakes from these foods with reduced risk for some types of cancer. The scientific evidence is not sufficient to conclude that beta-carotene in these foods is responsible for the protective effect. Beta-carotene has been shown to protect against chemical carcinogenesis in some animal models, and the biochemical and mechanistic data provide a plausible scientific basis on which to hypothesize a protective effect in humans.

3. Vitamin C

In the proposed rule, FDA recognized that mechanistic and animal studies suggest that vitamin C may reduce the risk of cancer through the mechanism of inhibition of nitrosamine synthesis. Cancer of the stomach is the likely site of highest N-nitroso compound exposure, and is the site for which the data were the most complete. However, FDA found that the data available at the time of the proposed rule were not

sufficient to establish the relationship between inhibition of N-nitroso compound synthesis and stomach cancer in humans. FDA also recognized, in the proposed rule, that higher intakes of fruits and vegetables, higher calculated intakes of vitamin C, and increased blood levels of vitamin C are associated with lower risk of cancer of the stomach, and, more weakly, with cancers at other sites. New studies that are relevant to these issues are reviewed in previous sections of this document.

Epidemiological studies published since the review for the proposed rule further support the association of fruits and vegetables and calculated vitamin C intakes with protection against certain types of cancer, especially cancer of the stomach.

The studies showing the relationship of N-nitroso compounds (a class of compounds with known carcinogenicity) to stomach cancer provide evidence for a mechanism by which a specific vitamin C effect might occur for this and other cancers (e.g., esophageal and uterine cervical). Formation of N-nitroso carcinogens in the stomach would be expected to have the greatest effect at the site of production and greatest exposure, the stomach, and lesser effects at distal sites that require absorption and translocation of the putative carcinogen before an effect could occur. In animal test systems, preformed N-nitroso compounds are multitarget organ carcinogens. These conclusions are consistent with the conclusions of the recent LSRO review (Ref. 39).

When considered together, the different types of data are suggestive, but not conclusive, that vitamin C may be responsible for at least part of the reduction in risk of stomach cancer associated with consumption of diets high in fruits and vegetables. The evidence for specificity of vitamin C includes epidemiological associations of decreased risk with higher intakes of vitamin-C containing fruits and vegetables, clinical trials that show decreased concentrations of N-nitroso compounds after vitamin C supplements, and epidemiological associations of higher concentrations of N-nitroso compounds with higher risk of stomach cancer and precancerous pathology of the stomach. However, the N-nitroso compound data have not generally been validated as a basis for establishing a relationship between vitamin C and risk of stomach cancer in the U.S. population. At present there is not significant scientific agreement that this mechanism is an etiologic factor in stomach cancer risk in the United States, or that qualitative or quantitative changes in production and excretion of nitroso-compounds are a risk factor for stomach cancer.

In order to allow the issue of intermediate or surrogate markers (such as formation of N-nitroso compounds) for cancer risk to be more fully evaluated, FDA will be convening an advisory committee in the near future to make recommendations which can then be applied to evaluations of data for determining the scientific basis for health claims relating antioxidant vitamin intakes to cancer risk.

4. Fruits and vegetables

Dietary patterns that are low in fat and high in plant foods, including fruits and vegetables, are generally high in vitamin C and provitamin A (beta-carotene), and other nutrients such as dietary fiber, and are associated with a decreased risk of some types of cancer. The mechanisms responsible for this relationship are not known. Several factors could be important contributors to this protective effect. For example, fruits and vegetables are low in fat. FDA has reviewed the evidence supporting the relationship between low fat diets and reduced risk of cancer and has concluded that there is sufficient scientific evidence and significant scientific agreement among qualified experts to support this relationship. (See the final rule on health claims for lipids and cancer published elsewhere in this issue of the **Federal Register**). FDA is, therefore, authorizing a health claim for fat and cancer. Thus, one possible mechanism whereby fruits and vegetables may contribute to reduced cancer risk is through displacement of higher fat foods in a diet, with a net effect of reducing total fat intakes.

The subject of this final rule relates to the possible protective mechanism of vitamins with antioxidant functions in reducing cancer risk. Three antioxidant vitamins were considered: Beta-carotene, vitamin C and vitamin E. Fruits and vegetables are the major food source of beta-carotene (pro-vitamin A) and vitamin C in the U.S. diet. Vitamin E is more ubiquitously distributed, but some vegetable oils and whole grain products are significant sources. Fruits and vegetables are also good sources of dietary fiber. The possible protective role of dietary fiber in reducing cancer risk has been discussed in the final rule on health claims for dietary fiber and cancer published elsewhere in this issue of the **Federal Register**.

Finally, fruits and vegetables contain a number of nonnutritional substances (e.g., indoles, phenols, flavones, and terpenes) which have been hypothesized to be possibly protective against cancer risk through antioxidant or other functions. Fruits and vegetables also contain many carotenoid compounds in addition to beta-carotene, the carotenoid which has the greatest pro-vitamin activity. While the other carotenoids do not contribute significantly, if at all, to vitamin activity, they are antioxidants and, thus, may also provide a protective effect against cancer risk. The specific roles of these numerous, potentially protective substances in plant foods are not yet understood, and knowledge of their content in fruits and vegetables is lacking. Consequently, dietary intakes of these substances have not been estimated in human studies which show associations between fruit and vegetable intakes and cancer risk.

B. Conclusion Based on Scientific Evidence

In conclusion, while populations with diets rich in fruits and vegetables experience many health advantages, including lower rates of some types of cancers, it is not possible to specifically determine that the two antioxidant vitamins (i.e., beta-carotene and vitamin C) which are contained in fruits and vegetables are responsible for this effect, or to rule out the possibility of significant protective effects from nonmeasured components in these fruits and vegetables. Since many of these food substances (both nutritive and nonnutritive) coexist in fruits and vegetables, an observed correlation between a measured nutrient may be reflective of a "true" correlation between a coexistent, nonmeasured food substance. Currently, there is not significant scientific agreement as to whether the observed protective effects of fruit and vegetable consumption against cancer risk are due to a single or combined effect of the antioxidant vitamins and other nutrients with antioxidant functions (i.e., selenium), to other nutritive components of such foods (such as dietary fiber), to unmeasured components of such diets (for example, nonnutritive components such as carotenoids, indoles or flavonoids), or to displacement of other known risk components (such as fats and calories) within the total diet.

Thus, the conclusion that diets low in fat and high in fruits and vegetables (foods which are low in fat and are generally good sources of vitamins A and C and dietary fiber) are associated with a reduced risk of cancer, is consistent with the available scientific evidence.

Because dietary patterns which have high consumption of fruits and vegetables are not only low in fat but

can also be characterized by high intakes of dietary fiber and vitamins A and C, these nutrients can serve as useful markers for identifying the types of foods which contribute to a dietary pattern that is associated with a reduced cancer risk. Calculated intakes of vitamin C and vitamin A (often but not always identifying the fraction from beta-carotene) from diets high in fruits and vegetables have been correlated with reduced cancer risk. Although it is not known if it is the antioxidant vitamin components or some other components of these diets that provide the protective effects against cancer, these nutrients are characteristic of protective foods. Therefore, FDA is authorizing the use on labels and labeling of health claims regarding the association between diets low in fat and high in fruits and vegetables and a reduced risk of cancer with specific mention that these diets and foods are generally rich sources of vitamin A (as beta-carotene), vitamin C, and dietary fiber.

V. Rationale For Final Rule

A. Relationship and Significance sections

New § 101.78(a) is consistent with the conclusions reached in the science review that it is fruits and vegetables which relate to the reduced risk of cancer, not the antioxidant vitamins per se. Yet, because of the usefulness of vitamins A (as beta-carotene) and C and dietary fiber in identifying fruits and vegetables most likely to correlate with reduced cancer risk, these nutrients are specifically identified as being characteristic of the protective dietary pattern. Any one or a combination of these three nutrients can serve as the identifying marker. Since fruits and vegetables are also characterized by their absence of fat, and because of the identified relationship of low fat diets to reduced risk of cancer, this also is required to be a characterizing nutrient for the type of dietary pattern associated with decreased cancer risk. Other components of the relationship statement, for example, risk factors, have been indicated, similar to other authorized health claims.

In new § 101.78(b), on the significance of the relationship between consumption of diets low in fat and high in fruits and vegetables and reduced risk of cancer, the summary includes the information that U.S. diets tend to be high in fat and low in fruits and vegetables. Discussion of current dietary guidelines on recommended servings of fruits and vegetables, and dietary fiber intakes are also given. Because of the coexistence of all of these nutrients in fruits and vegetables, and because all have been associated with reduced risk of cancer, all four nutrients are indicated. Because the mechanism of the protective effect is not known and because it is not known which of these nutrients is effective, or if some combination of these nutrients is effective, the health claim is focused on fruits and vegetables as a product class and their relationship to cancer risk.

B. Nature of the Claim

In § 101.78(c)(2)(i), FDA is authorizing health claims relating substances in diets low in fat and high in fruits and vegetables to reduced risk of cancer. In new § 101.78(c)(2)(i)(A), the agency is requiring, similar to other authorized claims, that the relationship be qualified with the terms "may" or "might." These terms are used to indicate that not all persons will necessarily benefit from these dietary changes. In new § 101.78(c)(2)(i)(B), the agency, consistent with other authorized claims, is requiring that the claim not indicate that all cancers may be affected, but rather that the risk of "some types of cancer" or "some cancers" may be reduced. The relationship of dietary factors to various types of cancers appears to be variable; in many cases, the available data are inadequate to specifically identify which cancers will be affected.

In new § 101.78(c)(2)(i)(C), the agency is requiring that the claim characterize fruits and vegetables as foods that are low in fat and contribute vitamin A, vitamin C, and dietary fiber to the diet. All four nutrients must be identified as characteristic of this dietary pattern. As noted in the conclusions reached from the available scientific evidence, it is not known what substances in fruits and vegetables are responsible for their protective effect. The best documented relationship is for fat and cancer. Roles for dietary fiber and vitamins A and C have been speculated and intakes of these nutrients from fruits and vegetables are correlated with cancer risk. By requiring that all characterizing nutrients be identified as characteristic of dietary patterns rich in fruits and vegetables without specifically attributing reduced cancer risk to a single nutrient, the claim is consistent with the current scientific knowledge. The claim should also minimize consumer confusion, since its wording is similar to current dietary guidelines from the U.S. Government, including the National Cancer Institute. New § 101.78(c)(2)(i)(D) requires the claim to specify that the food bearing the claim contains at least one of the following: Dietary fiber, vitamin A, or vitamin C. This statement is required in order to identify the contribution of the labeled food to the diet in an accurate and nonmisleading manner. Only those nutrients for which the labeled food qualifies as a good source under § 101.54 may be identified in the health claim. Although the regulation does not restrict the manner in which these nutrient levels may be described, terms used must be consistent with other labeling regulations.

In new § 101.78(c)(2)(i)(E), FDA, consistent with other authorized health claims, is prohibiting the attribution of a specific reduction in risk to diets low in fat and high in fruits and vegetables. In new § 101.78(c)(2)(i)(F), (c)(2)(i)(G), (c)(2)(i)(H), and (c)(2)(i)(I), FDA is prohibiting, similar to other authorized health claims, more specific use of dietary terms than is warranted by the current state of the scientific evidence. These requirements also standardize use of these terms, thus minimizing consumer confusion as they compare food labels across products, or as they compare a health claim to the nutrition information panel. Section 101.78(c)(2)(i)(J) requires that health claims indicate that development of cancer is dependent on many factors. This requirement is intended to prevent consumers from being misled that fruit and vegetable intake is the only factor connected with cancer risks.

C. Nature of the Food

New § 101.78(c)(2)(ii)(A) requires that the food bearing the authorized health claim be or contain a fruit or vegetable. Because the claim relates to diets high in those foods, it would not make sense for it to appear on the labeling of another type of food. A health claim that appears on a food that meets all the requirements in § 101.78(c)(2)(ii) but contains only a trivial amount of fruit or vegetables could be considered misleading and might misbrand the food under section 403(a) of the act.

FDA, consistent with the requirements for the health claim on fat and cancer (published elsewhere in this issue of the Federal Register), is requiring in new § 101.78(c)(2)(ii)(B) that foods bearing the authorized health claim be "low fat" foods or, alternatively, belong to a class of products that is "low in fat." Low fat diets are associated with reduced cancer risks. Low or negligible fat is also one of the characterizing nutrients for diets rich in fruits and vegetables. Since the effect of fat is not readily separated from the effect of other nutritive components of fruits and vegetables, it is required to be included as a qualifying nutrient.

In new § 101.78(c)(2)(ii)(C), FDA is requiring that fruits and vegetables bearing the health claim meet requirements for a "good source" (greater than or equal to 10 percent of the Reference Daily Intake (RDI)) for vitamin A and vitamin C, and greater than or equal to 10 percent of the Daily Reference Value (DRV) for dietary fiber. The requirement that these nutrients be present at 10 percent of the RDI or DRV is being established as a specific alternative to the 20 percent (i.e., "high") requirement for qualifying nutrients in the final rule on general requirements for health claims published elsewhere in this issue of the **Federal Register**. (See § 101.14(d)(2)(vii)). This alternate level was deemed useful to assure that most fruits and vegetables would be eligible for this health claim, because fruits and vegetables in general are the product class for which correlations with reduced cancer risk have been observed as opposed to specific fruits and vegetables. Moreover, as a product class, fruits and vegetables are significant sources of vitamins A and C and fiber in the U.S. dietary pattern. Without this alternative level very few fruits and vegetables would qualify for the health claim. This seems contrary to the available evidence and to the purpose of health claims.

This section also requires that the qualifying nutrients be based on "natural" levels in foods. This means that foods which require modification, for example, fortification with vitamins A or C or dietary fiber, in order to meet the qualifying criteria for the health claim, cannot bear the claim. This requirement is consistent with the scientific basis for the claim; that is, that fruits and vegetables in their native form correlate with reduced cancer risk. Since there are not sufficient data to specifically identify vitamins A and C and dietary fiber as causal, and because these nutrients are being used as markers for the substance(s) in fruits and vegetables that provide the observed effect, it is the native nutritional composition of the foods that identifies their usefulness. At the same time, this requirement does not prohibit fortification of qualifying foods with the characterizing nutrients, once the qualifying criteria have been met.

D. Optional Information

Under new § 101.78(d), similarly to other authorized health claims, health claims may identify additional risk factors for cancer. The regulation specifies the factors that may be listed; all are risk factors about which there is general scientific agreement. This additional information can provide a context that is useful for an understanding of the relationship of the diet to the disease, but, manufacturers are cautioned that it should not be presented in a way that is misleading to the consumer. A health claim may also indicate that reductions in fat intake and consumption of fruits and vegetables are part of a total dietary pattern that is consistent with the latest "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 40) published jointly by the USDA and the Department of Health and Human Services (DHHS). Consistent with other health claim regulations, the claim may also include information on the prevalence of cancer in the United States. In order to ensure that this information is valid, the agency is requiring that it come from one of three specified authoritative sources.

Additionally, for the health claim relating substances in diets high in fruits and vegetables to reduced risk of cancer, the agency is allowing the use of the term "beta-carotene" in addition to the term vitamin A in listing nutrients that are characteristic of the protective dietary pattern. Beta-carotene is the form of the vitamin which has antioxidant functions. Therefore, the use of this term is consistent with a possible mechanism of action. On the other hand, if, after a food meets the qualifying criteria for a health claim, the food is fortified with vitamin A (as retinyl palmitate or another form of preformed vitamin A rather than with beta-carotene), then it would be misleading to indicate that its vitamin A content is primarily beta-carotene. Thus, FDA is permitting the term beta-carotene to be used in the claim only when the vitamin A in the food bearing the claim is beta-carotene.

E. Model Health Claims

In new § 101.78(e)(1) and (e)(2), FDA is providing several model health messages to help manufacturers understand the requirements of new § 101.78 and to help them understand the type of health claim that FDA considers to be appropriate. FDA is not prescribing specific language for claims, but certain elements are required, and these models include the required elements.

VI. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VII. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), and along with the food labeling proposals, the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's disucssion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the dockts Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitues a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act, and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6, of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.71 is amended by adding new paragraph (d) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(d) Antioxidant vitamins and cancer.

3. New § 101.78 is added to subpart E to read as follows:

§ 101.78 Health claims: fruits and vegetables and cancer.

(a) *Relationship between substances in diets low in fat and high in fruits and vegetables and cancer risk.* (1) Cancer is a constellation of more than 100 different diseases, each characterized by the uncontrolled growth and spread of abnormal cells. Cancer has many causes and stages in its development. Both genetic and environmental risk factors may affect the risk of cancer. Risk factors include a family history of a specific type of cancer, cigarette smoking, alcohol consumption, overweight and obesity, ultraviolet or ionizing radiation, exposure to cancer-causing chemicals, and dietary factors.

(2) Although the specific roles of the numerous potentially protective substances in plant foods are not yet understood, many studies have shown that diets high in plant foods are associated with reduced risk of some types of cancers. These studies correlate diets rich in fruits and vegetables and nutrients from these diets, such as vitamin C, vitamin A, and dietary fiber, with reduced cancer risk. Persons consuming these diets frequently have high intakes of these nutrients. Currently, there is not scientific agreement as to whether the observed protective effects of fruits and vegetables against cancer are due to a combination of the nutrient components of diets rich in fruits and vegetables, including but not necessarily limited to dietary fiber, vitamin A (as beta-carotene) and vitamin C, to displacement of fat from such diets, or to intakes of other substances in these foods which are not nutrients but may be protective against cancer risk.

(b) *Significance of the relationship between consumption of diets low in fat and high in fruits and vegetables and risk of cancer.* (1) Cancer is ranked as a leading cause of death in the United States. The overall economic costs of cancer, including direct health care costs and losses due to morbidity and mortality, are very high.

(2) U.S. diets tend to be high in fat and low in fruits and vegetables. Studies in various parts of the world indicate that populations who habitually consume a diet high in plant foods have lower risks of some cancers. These diets generally are low in fat and rich in many nutrients, including, but not limited to, dietary fiber, vitamin A (as beta-carotene), and vitamin C. Current dietary guidelines from Federal Government agencies and nationally recognized health professional organizations recommend decreased consumption of fats (less than 30 percent of calories), maintenance of desirable body weight, and increased consumption of fruits and vegetables (5 or more servings daily), particularly those fruits and vegetables which contain dietary fiber, vitamin A, and vitamin C.

(c) *Requirements.* (1) All requirements set forth in § 101.14 shall be met.

(2) Specific requirements. (i) *Nature of the claim.* A health claim associating substances in diets low in fat and high in fruits and vegetables with reduced risk of cancer may be made on the label or labeling of a food described in paragraph (c)(2)(ii) of this section, provided that:

(A) The claim states that diets low in fat and high in fruits and vegetables "may" or "might" reduce the risk of some cancers;

(B) In specifying the disease, the claim uses the following terms: "some types of cancer", or "some cancers",

(C) The claim characterizes fruits and vegetables as foods that are low in fat and may contain vitamin A, vitamin C, and dietary fiber;

(D) The claim characterizes the food bearing the claim as containing one or more of the following, for which the food is a good source under § 101.54: dietary fiber, vitamin A, or vitamin C;

(E) The claim does not attribute any degree of cancer risk reduction to diets low in fat and high in fruits and vegetables;

(F) In specifying the fat component of the labeled food, the claim uses the term "total fat" or "fat";

(G) The claim does not specify types of fats or fatty acids that may be related to risk of cancer;

(H) In specifying the dietary fiber component of the labeled food, the claim uses the term "fiber", "dietary fiber", or "total dietary fiber";

(I) The claim does not specify types of dietary fiber that may be related to risk of cancer; and

(J) The claim indicates that development of cancer depends on many factors.

(ii) *Nature of the food.* (A) The food shall be or shall contain a fruit or vegetable.

(B) The food shall meet the nutrient content requirements of § 101.62 for a "low fat" food.

(C) The food shall meet, without fortification, the nutrient content requirements of § 101.54 for a "good source" of at least one of the following: vitamin A, vitamin C, or dietary fiber.

(d) *Optional information.* (1) The claim may include information from paragraphs (a) and (b) of this section, which summarize the relationship between diets low in fat and high in fruits and vegetables and some types of cancer and the significance of the relationship.

(2) The claim may identify one or more of the following risk factors for development of cancer: Family history of a specific type of cancer, cigarette smoking, alcohol consumption, overweight and obesity, ultraviolet or ionizing radiation, exposure to cancer-causing chemicals, and dietary factors.

(3) The claim may use the word "beta-carotene" in parentheses after the term vitamin A, provided that the vitamin A in the food bearing the claim is beta-carotene.

(4) The claim may indicate that it is consistent with "Nutrition and Your Health: Dietary Guidelines for Americans," U.S. Department of Agriculture (USDA) and the Department of Health and Human Services (DHHS), Government Printing Office.

(5) The claim may include information on the number of people in the United States who have cancer. The sources of this information must be identified, and it must be current information from the National Center for Health Statistics, the National Institutes of Health, or "Nutrition and Your Health: Dietary Guidelines for Americans," USDA and DHHS, Government Printing Office.

(e) *Model health claims.* The following model health claims may be used in food labeling to characterize the relationship between substances in diets low in fat and high in fruits and vegetables and cancer:

(1) Low fat diets rich in fruits and vegetables (foods that are low in fat and may contain dietary fiber, vitamin A, and vitamin C) may reduce the risk of some types of cancer, a disease associated with many factors. Broccoli is high in vitamins A and C, and it is a good source of dietary fiber.

(2) Development of cancer depends on many factors. Eating a diet low in fat and high in fruits and vegetables, foods that are low in fat and may contain vitamin A, vitamin C, and dietary fiber, may reduce your risk of some cancers. Oranges, a food low in fat, are a good source of fiber and vitamin C.

Dated: November 3, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

papilloma virus age, parity, ual period, ve practice and mber of per day and years obtained atient. Venous ined for nt analysis: id, beta- d retinol. id levels were ly lower in gardless of atus or f human irus infection.	Analysis directed at serum antioxidant levels in smokers versus nonsmokers. After dividing smokers and nonsmokers into groups, there was no significant difference in ascorbic levels in the women with cervical dysplasia and those without. Although not noted in the paper the serum retinol level was lower in smokers with cervical dysplasia than those without and serum beta-ccarotene levels were lower in smokers with cervical dysplasia than those without.	The study group was small, and both cigarette smoking and antioxidant level are continuous variables. The results do not show a significant association between cervical dysplasia and serum antioxidants.
uency re with data on as was used. quency of in previous od. Local food tables used to take. Age, sex, ears prior to meals per day, n years, and physical workplace for energy) were used in model.	There was no significant association between the risk of either colon or rectal cancer and level of vitamin A, retinol, carotene, vitamin C, or vitamin E intake.	Based on the significant inverse association between fiber from legumes and folic acid in cruciferous vegetable, the findings support a recommendation for diets high in vegetables, along with a healthy lifestyle including moderate intake of calories and adequate physical activity.

Methods	Results	Comments
formation by assessed for the rs before onset ease. All were coded by . Data were n vitamin C urce of water ars of or use, and use for smoking meat Risk estimates ned by nal logistic methods.	A low intake of vitamin C relative risk (RR) = 2.32, 95% confidence interval (CI) 1.22 to 4.43 for lowest against highest quintile), noncentralized water supply (RR = 2.17, CI 1.14 to 4.13 against central water supply), refrigerator use for less than 25 years (RR = 1.33, CI 0.82 to 2.15 against more than 30 years, and use of spruce for smoking (RR= 3.33, CI 1.56 to 71.2) against not smoking meat at home), were identified as factors possibly causally related to stomach cancer occurrence.	The results are consistent with the hypothesis that increased intake of vitamin C reduces the risk of stomach cancer by inhibiting nitrosation reactions in the stomach, or by decreasing the carcinogenicity of putative carcinogens in smoke (especially polyaromatic hydrocarbons and nitrosamines). Also, the data implicate possible sources of carcinogens or carcinogen precursors (smoked meat and local water supply) in the occurrence of stomach cancer.
ed questionnaire occupation, ocioeconomic ietary factors types and amounts ten. Diet into five types; ich in animal fat, egetable fat, in vitamin A, and in vitamin C. osition based on a. Odds ratio iet, obesity and cancer d.	This study found no association between a diet deficient in vitamins A or C and the risk of prostatic cancer. The relationship between intake of vegetable fats and prostatic cancer was also not significant.	The diet of central Spain is rich in fruits and vegetables. It is possible that even the lowest quintile of intake for fruits and vegetables in Mediterranean areas are relatively high in relation to other cuisines. The results of this study may not be generalizable.
using dietary aire containing items; dietary t covered year terview; 68% of histologically ; others diagnosed y.	Adjusted for smoking and total calories: Daily consumption of vegetables statistically significant Inverse association between intake of fresh vegetables, cooked cruciferous vegetables and pancreatic cancer. e nutritional that included chemical and ds. The s allocated roups: intake thout intake ≥50 t supplements, y with Followup es determined for several es, including art disease.	Higher dietary intakes of ascorbic acid were associated with significant reduction total mortality rate and in the mortality from heart disease. These effects were enhances by supplements. The standardized mortality rate from cancer (total for all sites) was a nonsignificant 0.78 with supplemental ascorbic acid. In contrast with the results for total mortality and heart disease mortality, the results with cancer mortality were not significant because the standardized mortality rate was not a low and because the cohort size was decreased (heart disease produced approximately 40 percent of the total mortality, whereas cancer produced less than 25 percent).	These results do not provide support for a reduction in risk of any type of cancer by ascorbic acid. They cannot be interpreted, however, as contradicting that possibility. The mortality rate from cancer was not reduced as much with elevated vitamin C intake as were the total and heart disease rates, and the cohort size was substantially smaller. Any protective effect of vitamin C at one cancer site may have been masked by no effect at other sites, with the overall rate being apparantly changed by a substantial but nonsignificant amount (22 percent) in a protective direction.
of zinc, ium, vitamins ured. ls of amins E and C most subjects. city codes	Significantly higher mean levels of vitamin E, total cholesterol and E/total cholesterol ratio found in breast cancer cases than in controls. Effect lost when vitamin pill users excluded, except vitamin E. Leukocyte vitamin E level also significantly higher. Serum Zinc level sign higher. Elevated leukocyte vitamin C in cases borderline sign. Mean leukocyte vitamin E level sign after vitamin pill users excluded.	Sample size small. Elevated plasma vitamin E, leukocyte vitamin E, serum Zinc in breast cancer cases hypothesized to relate to facilitation of certain tumor growth by these antioxidants suggesting effect ultimately related to metabolic alteration. Future studies need to correlate tumor antioxidant level to resistance (chemo or natural) and tumor antioxidant level to blood level.

ing dietary s on 172 foods; d 2 years view; all cases gically esults adjusted cation, age at ncy, number of age at lative with r, and benign se.	Cases and controls consumed same number of calories. Dietary carotene, vitamin C protective but no effect shown for supplement use; dietary fiber borderline protective RR = 0.7 (0.5 to 1.1); adjustment for total calories did not change results. Cases ate less of 10 fruits and vegetables in questionnaire.	Low participation rates may introduce bias: 56% of eligible cases and 46% of eligible controls participated in study, thus may not be able to generalize the results.
re administered formation on variables, alcohol use, tion, and ory. Vitamin se questions ars of use, age es of products used rand) and uses trient vitamin shots d mineral d.	Use of supplements was significantly associated with reduced risk of oral cancer. Use of supplements was associated with being female, white, more highly educated, being a California resident, having a lower body mass, and consuming more fruits and vegetables. Protracted use did not increase the apparent effects of supplements on cancer risk. Users of supplements of individual vitamins, including A, B-complex, C and E were at lower risk after controlling for effects of tobacco, alcohol and other risk factors. After adjustment for use of other supplements, vitamin E supplementation was the only one that remained associated with reduced risk.	It is not clear that the lower risk among consumers of vitamin E supplements was due to the vitamin itself, because the finding are also associated with higher intakes of fruits and vegetable among supplement users. The findings are consistent with evidence from experimental animals, and should prompt further research on vitamin E in reducing the risk of cancer.

Methods	Results	Comments
s were conducted year of diagnosis perienced er who was the all subjects. The er was not blinded agnosis. The naire covered history and usual intake during the ceding diagnosis. n carotene values foods are for beta-.	Calculated mean dietary intakes of beta-carotene were 24% lower for lung cancer cases than for controls, 10% lower for other epithelial cancer cases than for controls. Serum concentrations of beta-carotene, retinol, and vitamin E were lower in the cancer patients than in the controls by 58, 30, and 31 percent, respectively, for lung cancer, and 33, 11, and 14 percent, respectively for other epithelial cancer cases. The OR's were less than 1.0 in the two upper thirds of dietary carotene, with the trends having borderline significance. The OR's for intakes of fruits and vegetables were rather irregular, and the associated trends were weaker than the trends for beta-carotene.	The period of concern in the recall was the year prior to diagnosis, a time. By comparison, cases in the 2-year period following sampling or interview are often excluded from prospective studies because differences may be caused by the cancer. The results suggest that beta-carotene is protective against epithelial cancers, including lung cancer.
nt of consumption ods, including urces of vitamin A, enoids, and folacin as medical and al characteristics to cervical cancer. for age, study xual and tive history, nomic status, g practice, and n of human a virus.	Slightly lower risk for highest quartiles of consumption of fruit and fruit juice. Risk of cervical cancer not reduced in groups with highest consumption vegetables, foods of animal origin, complex carbohydrates, legumes, of folacin-rich foods. Evaluation of nutrient indices identified decreased risk associated with vitamin C, beta carotene, other carotenoids. Including vitamin C and beta carotene in the same model attenuated the association for beta carotene, but not for vitamin C.	Results consistent with other studies that support a protective effect of nutrients in fruits and vegetables against the development of invasive cervical cancer, however specific category of nutrient responsible not readily apparent. Associations were driven by relationships between diet and cervical cancer at two study sites. Higher socioeconomic status of subjects at these sites leaves open possibility of selection bias or an unidentified dietary pattern.

TABLE 1--

Study	Study Design	Subjects	Metho
Knight et al., 1991. (Ref. 27)	Clinical trial of nitrosation of L-proline load by diet-derived nitrate, and inhibition by dietary ascorbic acid.	The first study had 16 subjects of both sexes, aged 23 to 56 years, all nonsmokers. The second study had 19 females aged 20 to 28 years, including 5 smokers. All subjects avoided known sources of the nitrosation product and vitamin supplements for 72 hours before test meal consumption.	Test Meal 1 was supply a high le dietary nitrate mg/meal) accompa relative low lev ascorbic acid (2 Test Meal 2 cons the same items a 1, with the addi foods rich in as (340 mg/meal). level of Test Me 197 mg. Both te contained 2.4 g proline. In the study, nitrosati determined after consumption of acid meal (Test and, a week lat consumption of meal with 500 m L-proline. The nitrate st Meal 2 was th test meals .4 g dietary n the first rosation was after of low ascorbic Test Meal 1) later, after of the same 500 mg of added In the second subjects had determined with ine, first with corbic acid meal week later with scorbic acid. ne was collected rs after each and assayed for line (NPRO) and	In the first study, the background excretion of NPRO was increased by addition of free L-proline. In the second study, a lower excretion of NPRO occurred with the high ascorbic acid meal. This occurred despite a slightly 13 higher nitrate intake from Test Meal 2, compared with that from Test Meal 1. Some subjects (Subgroup A) had a low NPRO excretion after Test Meal 1, this level was maintained with Test Meal 2. Subgroup B had high excretion of NPRO after Test Meal 1, and this was strongly decreased after Test Meal 2, containing high ascorbic acid foods.	Six subjects showed no change in NPRO after consumption of a test meal containing rich sources of ascorbic acid. These had low NPRO excretions with the low ascorbic acid meal. 13 subjects had much higher levels of NPRO excretion after the low ascorbic acid meal, but this was strongly inhibited by the inclusion of rich ascorbic acid sources in the meal, even though the ascorbic acid sources contributed some additional nitrate. The data suggest that not all individuals synthesized NPRO in vivo from the ingested precursors, and those who did not were the subjects who failed to show ascorbic acid inhibition of NPRO excretion. It was concluded that a normal western diet with plentiful content of fresh vegetables can provide sufficient nitrate to result in endogenous nitrosation, and that this process is substantially inhibited by inclusion of ascorbic acid rich foods.

ry estimated l habitual evious year. ioxidant d on blished Finnish foods.	Inverse relationship between intake of vitamins A, E, and C and incidence of lung cancer in nonsmokers. Relative risk between lowest and highest tertile of intake 2.5, 3.1 and 3.1 respectively. Inverse gradient between yellow, green and red vegetables (source of carotenoids) and lung cancer. No inverse gradient between preformed vitamin A and lung cancer. Strong inverse association for margarine intake (source of tocopherol) and incidence of lung cancer; significant inverse gradient for fruit intake (vitamin C source) despite low intake in this cohort.	Misclassification of intake and changes in intake were possible over followup, especially supplement use. Other substances in foodstuffs rich in antioxidant vitamin (e.g., terpenes, flavones, and phenols) may be anticarcinogenic. Studies needed on dietary patterns, intake levels, and protective effects of other constituents of diets.
primary cancer diagnosis om the cancer re linked to ed in the health data. Serum ons were form alpha- beta-carotene, tinol-binding d selenium.	The crude mean level of serum alpha-tocopherol was 30% lower in persons with melanoma than in controls. The laryngeal and esophageal cases had alpha-tocopherol levels that were nonsignificantly lower. Accordingly for alpha-tocopherol, the relative risks of melanoma and was 0.2 (significant) and for cancers of the larynx and esophagus, 0.48 and 0.39 (nonsignificant). For beta-carotene, the relative risk of melanoma was 0.03 (highly significant).	Only melanoma patients had significantly lower serum alpha-tocopherol and beta-carotene levels than controls. Because the numbers of cases were small, no strong conclusions can be drawn from the results until they are confirmed in studies based on larger cohorts or on pooled data from several small samples.

els of eight ients measured in l controls. Stage ancer patients luded to minimize f disease on markers.	Intake of retinol, cryptoxanthin, lycopene, alpha carotene, lutein and alpha tocopherol did not significantly differ between cases and controls. After adjustment for age, study site, sex and reproductive history, socioeconomic status, and papilloma virus higher serum beta carotene and gamma tocopherol levels associated with decreasing risk of disease.	Serum beta-carotene level constant as disease progressed, arguing against effect of disease progression on nutrient value, while gamma tocopherol level was higher in cases and progressed with disease. In this study dietary and serum effects of beta carotene concordant, both parameters indicate a possible association between intake of beta carotene and reduced risk of invasive cervical cancer.
corbic acid and juice nitrite and ractable N-nitroso were determined reatment, weekly weeks of ascorbic atment (4 g/day) weeks after nuation of t. All patients their normal ut avoided and fruit juices he experiment.	Many patients had low baseline serum levels of ascorbic acid, and compliance with treatment was confirmed by a marked rise during treatment. The levels were still high 4 weeks after the patients had been instructed to stop taking ascorbic acid, implying that many of them had not discontinued treatment. Baseline levels of N-nitroso compounds were high in all groups compared with the levels previously found in normal controls, but a highly significant decrease was observed during treatment with ascorbic acid in all groups except those with PA. Treatment produced a marked decrease in gastric juice nitrite levels in all groups except those with PA.	These data support the conclusion that high-dose ascorbic acid treatment reduces the intragastric formation of nitrite and N-nitroso compounds.

Methods	Results	Comments
v using dietary naire containing 60 ups; dietary nt covered year nterview. Cases ically confirmed.	Adjusted for smoking and total calories, a higher vitamin E intake was associated with a marginally significant reduction in risk of bladder cancer. No association found for retinol or carotene intake.	Slightly low participation rates (cases: 72% and controls: 71% bospital and 66% population); results possibly biased by inclusion of 208 prevalent cases who may represent survivors of bladder cancer.
w using dietary naire on 55 foods; diet assessed, but ed over past 12 former diet was l cases were ically confirmed; adjusted for age, al status, family of breast cancer, of benign breast alcohol ion, and age at .	Antioxidant vitamin intake had no significant effects on risk of breast cancer in premenopausal women and postmenopausal women; however, fruits rich in beta-carotene had a marginal protective effect (RR=1.4, CI=1.0-2.0) on breast cancer in this same group. In post-menopausal women retinol had a marginal protective effect (OR 1.8, CI=1.2-2.8), Beta-carotene and vitamin E intake had no significant effects on risk of breast cancer.	Study adds support to the hypothesis that fruit consumption may have a slight protective effect against breast cancer in all women (both premenopausal and postmenopausal women).

Methods	Results	Comments
were diagnosed by . Urinary acid and nitrate rmined chemically. agenicity was d in the Ames test monella um TA98 and TA100 each with and n activating S9 Four individual otal N-nitroso were chemically n gastric juice.	The reduced ascorbic acid content of urine was lower in the gastric cancer group than in normal controls, while the content of nitrate was significantly higher in the cancer patients than in the controls. No mutagenicity was seen in the urines of the controls, whereas a low fraction of the urines from the dysplasia patients and a high fraction of the urines from the gastric cancer patients were mutagenic.	The lower excretion of ascorbic acid in the urine of gastric cancer patients could be either a cause or a result of the disease, but it is consistent with the hypothesis that this vitamin reduces the risk of this disease. The higher excretion of nitrate probably reflects a higher intake. Mutagenicity of the urine was directly associated with severity of pathology of the stomach. Normal controls had low levels of N-nitroso compounds in gastric juice, compared with chronic atrophic gastritis, dysplasia, or gastric cancer. The mutagenicity of the urine may have been related to synthesis of N-nitroso compounds in the stomach and differences in this process may have been due to differences in intakes of ascorbic acid and nitrate. These results support the hypothesis that N-nitroso compounds may be the cause of gastric cancer.

les of 12-hour t urine were d from the children ey had ingested 500 ne with 200 mg acid or 500 mg alone 1 hour after ing meal. Urine were assayed for N- roline and two nitroso compounds, ate.	All comparisons of levels of N-nitroso-proline were statistically significant. Thus, in both areas, the level was reduced by ingestion of ascorbic acid with proline, compared with that seen with proline alone. The level as higher in the high-risk area than in the low-risk area, for each type of dietary treatment. The N-nitrosoproline level correlated well with nitrate levels.	The results indicate that children living in a high-risk area have a higher potential for endogenous nitrosation than those living in the low-risk area. Nitrate exposure may explain at least part of this difference. The data confirm that proline nitrosation can be substantially inhibited by ascorbic acid supplementation.
fasted overnight. juice aspirated for acid, total C, total bile acid, , nitrate and total compounds (NOC's), liquot of plasma lected for vitamin C 2 stomach biopsies; ed for Helicobacter bmitted for thology.	Of 56 patients, 12 completely normal on histopathology, 18 chronic superficial gastritis, 17 chronic gastritis with atrophy, and 9 had gastric reflux. 89% of chronic gastritis had Helicobacter infection. Intestinal metaplasia in this group significantly associated with gastric ascorbic acid, gastric vitamin C.	Age and gastric pH also significantly higher in chronic gastritis patients with intestinal metaplasia versus those without.

Methods	Results	Comments
were identified with y-confirmed cervical epithelial neoplasia of grades I, II, or Participants ted a food frequency ionnaire provided by ational Cancer tute. The conversion ods to nutrients was rmed with and without justment for energy e.	For serum lycopene, the odds ratios for CIN were significantly increased in the three lower quartiles. The finding for lycopene-rich foods were consistent with this result. CIN was not associated with lutein. Finding for alpha-carotene, beta-carotene and cryptoxanthin were ambiguous. The lower quartiles of dietary vitamin C were associated with significantly increased odds ratios for CIN.	The relatively low response rates (approximately 60 percent for cases and 50 percent for controls) could have introduced bias. An inherent limitation of case-control studies is the determination of exposure after the onset of disease, especially for serum studies--dietary behavior may have changed after diagnosis and before blood sampling. The finding of a protective association for lycopene but not other carotenoids indicates that caution must be used in attributing the effects of carotenoid-containing fruits and vegetables to beta-carotene, at least for this type of cancer.
logically confirmed and controls viewed using itative food-frequency ionnaire. Data was zed separately for e (45 to 67) and older o 74) age categories y tumor ssiveness.	Beta carotene had a nonsignificant protective effect for prostatic cancer in younger males. In older males, total vitamin A had a slight positive association with all prostate cancer OR=1.6, CI=0.9 to 2.4). There was little association vitamin C and beta-carotene and prostate cancer in older men.	The most significant association were seen for older males with aggressive tumors. Dietary fat was the strongest risk factor for these males. It was not possible to blind interviewers to the case or control status of respondents.
y-four hour urine es and gastric juice an overnight fast collected and assayed -nitroso-proline and ther N-nitroso unds.	Levels of N-nitroso compounds in the urine were higher in subjects with gastric dysplasia than in normal controls or subjects with chronic atrophic gastritis/intestinal metaplasia. Levels of N-nitroso compounds were lower in gastric juice than in urine, and levels in gastric juice could not be evaluated by gastric pathology.	Persons with gastric dysplasia had elevated urinary levels of N-nitroso compounds, and these subjects are exceptionally prone to stomach cancer.

uce samples were ed with ethyl and the extract was ted with sodium under simulated conditions. icity was determined e Ames test using lla typhimurium TA100, a sister ic exchange assay, icronucleus test. nal carcinogenicity as performed by g for 3 days either ted or nonnitrosated uce extract to rats and ning the effects in topsied after 4 or s. A total of 39 juice samples were ed from patients n overnight fast by doscopy.	In the absence of nitrosation, none of the fish sauce extracts was mutagenicity. After nitrosation, all samples had direct mutagenicity in the Ames test and induced sister chromatid exchange with a dose-response relationship. In the micronucleus test, fish sauce extracts from only two villages were active. Four weeks after treatment with fish sauce, only those rats treated with the sauce that was mutagenic in all three assays showed marked precancerous dysplasia. After 16 weeks, the same treatment group had cancerous ulceration in the glandular stomach, with dysplastic glands and cells that had penetrated the mucosa and infiltrated into submucosa and muscular layers of the gastric wall. The mean concentrations of N-nitrosamides in the nitrosated fish products were more than 15 times higher in the samples from a high-risk area than in the samples from a low-risk area. The N-nitrosamide concentrations in gastric juice were strongly positively correlated with the severity of pathological changes in the stomach.	These data strongly support the hypothesis that the etiology of human gastric cancer is closely related to intragastric formation of mutagenic/carcinogenic N-nitroso compounds, that the degree of pathological change is directly related to the exposure of these compounds, and that exposure to these carcinogens is higher in areas of high-risk for stomach cancer.

ethods	Results	Comments
ns had been to 14 years at of -20 to -75° was analyzed opherol.	In comparison of cases versus controls, alpha-tocopherol values were consistently nearly equal, and, when numerical difference occur, the cases tended to be slightly lower than the controls. The crude OR's for colon and rectum cancer were consistently lower for the highest quartile of serum alpha-tocopherol values than for the lowest quartile. The CI's of the collective data were quite wide, preventing significance of any real effects.	The results suggest that serum alpha-tocopherol concentration may be inversely related to risk of colorectal cancer. This is unclear, however, because the association between serum alpha-tocopherol level and decreased risk was modest, the confidence were wide, and the overall tests for trend in effect were not significant. Larger observational studies with dietary data are needed to determine whether vitamin E has a small but important effect on risk of colorectal cancer.
ire was mailed cts. Response for non- tes. Food determined for foods. Annual regard to ion, and ord information detect new	Fruit consumption had a strong protective effect for lung cancer; RR = 0.26 for highest tertile of consumption, CI = 0.10-0.70, p = 0.006.	This population is unique in that less than 4 percent admitted to smoking and approximately 50 percent are lacto-ovo vegetarians.
mples were m 2,974 men in examination rmation about btained from d death obtained. No tics were eight	Overall cancer mortality was associated with low mean plasma carotene level adjusted for cholesterol, and vitamin C. Bronchus and stomach cancers were associated with low mean plasma carotene. Stomach cancer was associated with low mean vitamin C and lipid-adjusted vitamin A. Low levels of vitamin C increased the risk of stomach cancer (RR = 2.17, p = 0.05; and gastrointestinal cancer, RR = 2.46 in older subjects, significance lost in this group of subject with exclusion of first 2 years of followup.	Authors conclude that low serum antioxidant vitamin levels are associated with higher risk of subsequent cancer. Effects appear to be site specific. The role of nutrient intake, rather than serum levels, and other variables is unclear. Serum lipid, smoking, exercise, unidentified nutrients are associated with antioxidant vitamins may effect serum levels.

hods	Results	Comments
conducted on n, tobacco, raphics, and . Questions t 61 food od d recent . Indices e data were HANES II.	All fruits and vegetables, except legumes were associated with decreased risk of cancer in men. A significant protection was associated with intake of noncitrus fruits, green leafy vegetables, and vegetables eaten raw. All fruits and vegetables, except dark yellow vegetables, especially cruciferous vegetables, were associated with decreased risk of cancer in women. A protection was most evident for pharyngeal cancer. Intakes of carotene and vitamin C were associated with significantly reduced risk in men, while vitamin C was significant for reduced risk in women.	Lower consumption of fruits and vegetables in blacks may contribute to elevated rates of oral and pharyngeal cancer versus general population. The study is consistent with a protective role of the antioxidant vitamins and also for the inducer compounds in cruciferous vegetables.
ere asked to frequency in a interview for and vitamin ring the nutrient sed to es.	A significant increase in risk of pharyngeal cancer was associated with low intake of vitamin C; RR = 2.5, CI = 1.5 to 4.2. The role of vitamin C supplementation was difficult to assess because of discrepancies between next of kin reporting and the remaining case group.	The study suggests a potential protective effect of vitamin C against pharyngeal cancer. The authors conclude that the data are compatible with other research reporting a protective effect of fruits and vegetables against pharyngeal cancer.

[Docket No. 91N-0102]

RIN 0905-AD08

Food Labeling: Health Claims; Zinc and Immune Function in the Elderly

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision not to authorize the use on the label or labeling of foods of health claims relating to an association between ingestion of zinc and immune function in the elderly. This rule is issued in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims, and is developed in accordance with the final rule on general requirements for health claims, issued elsewhere in this issue of the Federal Register. The agency has concluded that, based on the totality of the scientific evidence, there is not significant scientific agreement among qualified experts that increased intake of zinc will enhance immune function in the elderly. Therefore, FDA has concluded that claims on foods relating to zinc and immune function in the elderly are not justified.

EFFECTIVE DATE: May 8, 1993.

FOR FURTHER INFORMATION CONTACT: James E. Hoadley, Center for Food Safety and Applied Nutrition (HFS-227), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-205-5593.

SUPPLEMENTARY INFORMATION:

I. Background

In the Federal Register of November 27, 1991 (56 FR 60652), FDA proposed not to authorize health claims relating to zinc and immune function in the elderly. The proposed rule was issued in response to provisions of the 1990 amendments (Pub. L. 101-535) that bear on health claims and in accordance with the proposed general requirements for health claims for food (56 FR 60537, November 27, 1991). As amended in 1990, the Federal Food, Drug, and Cosmetic Act (the act) provides that a food is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition unless the claim is made in accordance with section 403(r)(3) or (r)(5)(D) of the act (21 U.S.C. 343(r)(3) or (r)(5)(D)).

Congress enacted the health claims provisions of the 1990 amendments to help U.S. consumers maintain good health through appropriate dietary patterns and to protect consumers from unfounded health claims. Section 3(b)(1)(A) of the 1990 amendments specifically requires the agency to determine whether claims respecting 10 nutrient/disease relationships meet the requirements of section 403(r)(3) or (r)(5)(D) of the act. The relationship of zinc and immune function in the elderly is one of the claims required to be evaluated. In the proposed rule (56 FR 60652), FDA reviewed the publicly available relevant data pertaining to zinc and immune function in the elderly and evaluated whether health claims relating zinc and immune function would be justified under the standard proposed in the companion document entitled "Food Labeling: General Requirements for Health Claims for Food" (56 FR 60537).

FDA published a notice in the Federal Register of March 28, 1991 (56 FR 12932), requesting scientific data and information on the 10 specific topic areas identified in the 1990 amendments, including zinc and immune function in the elderly. Relevant scientific studies and data received in response to this request were considered as part of the agency's review of the scientific literature on zinc and immune function, and were included in the proposed rule (56 FR 60652).

In the proposed rule (56 FR 60652), FDA requested written comments on its tentative determination not to authorize a health claim for zinc and immune function in the elderly. In addition, FDA held public hearings on January 30 and 31, 1992, on all aspects of the proposed rules published to effect the 1990 amendments (57 FR 239, January 3, 1992). The agency received approximately 20 comments in response to its proposal to deny health claims regarding zinc and immune function in the elderly. Several comments were received that were more appropriately addressed in other documents, and these comments were forwarded to the appropriate docket for response.

The relevant publicly available data evaluated by FDA in its proposed rule (56 FR 60652) included seven human studies (Refs. 29 through 35) in which elderly subjects were supplemented with zinc to determine its influence on immune system function. In the proposed rule (56 FR 60652 at 60661), the results of four of the earlier published studies (Refs. 29 through 32) suggested a zinc-associated enhancement of several measures of immune function. However, FDA noted that the reliability of three of these studies was limited due to inclusion of very few individuals, and the tested subjects were not representatives of the general elderly population. Moreover, FDA further noted that the results of these initial reports have not been substantiated by more recent, larger studies of more rigorous experimental design (Refs. 34 and 35).

FDA tentatively concluded that the later, larger studies showed no improvement of immunocompetence from zinc supplementation in the elderly. The agency also pointed out that zinc supplementation at levels in excess of 100 milligrams per day (mg/day) can result in suppression of immune system function (Ref. 48). For these reasons, FDA tentatively determined that claims on foods, including dietary supplements, relating to zinc and immune function in the elderly are not justified.

The Dietary Supplement Act of 1992 established a moratorium on the implementation of the 1990 amendments with respect to dietary supplements. The law says that FDA can grant health claims for foods, including dietary supplements, using the significant scientific agreement standard specified in section 403(r)(3)(B)(i) of the act. However, it may not act on such claims under section 403(r)(5)(D) of the act until it establishes a standard to implement that section of the act, which the new law says may not occur until December 1993. Section 3(b)(1)(A)(x) of the 1990 amendments directs the agency to evaluate the zinc and immune function claim based on the standard that FDA is establishing for determining the reliability of health claims under section 403(r)(5)(D) of the act. In the November 27, 1991 proposal, on general requirements for health claims, FDA proposed to adopt the standard that the 1990 amendments provide for conventional foods, which is set forth in section 403(r)(3)(B)(i) of the act, as the standard for dietary supplements. Given this fact, and the fact that zinc is found in numerous conventional foods as well as in dietary supplements, FDA broadened its inquiry to a determination as to whether it should grant a health claim on zinc and immune function in the elderly on any foods.

Because the Dietary Supplement Act provides that FDA may grant claims under section 403(r)(3)(B)(i) of the act, and given the breadth of FDA's November 1991 proposal, on zinc, FDA has decided to move forward to

determine whether it can authorize a claim under section 403(r)(3)(B)(i) for zinc and immune function.

However, this rule does not apply to dietary supplements. While a manufacturer of a dietary supplement can make a claim on zinc and immune function in the elderly without rendering its product misbranded under section 403(r)(1)(B) of the act, the manufacturer should assure itself that the making of the claim will not misbrand the product under section 403(a) of the act.

II. Comments to the Proposal and the Agency's Responses

A. General

1. Nine comments representing State attorney generals, State agencies, associations of public health officials, and professional associations of people employed in nutrition-related fields agreed with FDA's assessment of the evidence on zinc and immune function, including FDA's proposed decision not to authorize a claim on this nutrient-disease relationship. Several comments stated opposition to allowing health claims in general.

The agency acknowledges those comments supporting its tentative position not to authorize a health claim on zinc and immune function in the elderly. In response to those comments that oppose all health claims, however, the agency points out that the 1990 amendments provide sufficient safeguards to ensure that health claims are scientifically valid and will provide consumers with information that will promote good health.

B. Comments on the Available Data

2. One comment from a consumer-oriented nutrition magazine noted that the small number of participants in some of the studies cited in the proposed rule (56 FR 60652) makes their inclusion questionable. This comment also noted that results from studies using supplemental zinc levels no higher than the Recommended Dietary Allowance would likely be of little value.

FDA concurs with this comment. In its proposed rule, FDA noted that small (5 to 8 subjects), uncontrolled studies (Refs. 30 through 32) were included among those that it found in its review of the publicly available scientific literature. However, in the proposed rule, the agency stated that the significance of these reports to the agency's decision was limited because of the small number of subjects and the lack of substantiation of their findings by larger studies.

Of the three studies in which supplemental zinc was provided at the Recommended Dietary Allowance level (12 to 15 mg/day), two studies (Refs. 34 and 35) also included substantially higher supplemental zinc levels (100 mg/day). FDA stated that the third study (Ref. 31), which used a 15 mg/day zinc supplement, was of low reliability because of the limited number of subjects, absence of control subjects with which to compare those supplemented with zinc, and lack of blinding as to treatment received.

3. One comment submitted a list of recently published scientific studies, not cited in the proposed rule, suggesting that they bear directly or indirectly on the issue.

FDA reviewed the submitted studies and determined that not one of the articles is relevant to the topic of zinc and immune function in the elderly. Of the six references listed, five were of studies of zinc metabolism or nutrition, but did not involve immune function. One reference listed did concern zinc and immune function, but was available only as an abstract. FDA did not consider abstracts in its evaluation as experimental design and data are presented too briefly for adequate evaluation.

C. Life Science Research Office Report

4. Among the authoritative documents considered in the proposed rule was a preliminary report (Ref. 26) from a 1991 review of the literature on the relationship between zinc and immune functions in the elderly conducted by the Life Sciences Research Office (LSRO) of the Federation of American Societies of Experimental Biology (FASEB). The final version of the LSRO report ("Evaluation of Publicly Available Scientific Evidence Regarding Certain Nutrient-Disease Relationships: 2. Zinc and Immune Function in the Elderly", W. R. Beisel) was released by LSRO in December 1991, and filed in the docket as a comment on the proposed rule. The final version was not changed from the preliminary version cited and discussed in the proposed rule. It fully supports FDA's conclusions on the lack of a relationship between zinc and immune function in the elderly.

D. Canada

5. In two comments, the Canadian Government (Bureau of Consumer Affairs, and Health and Welfare Canada) noted that, under the Canadian Food and Drug Act, Section 3, the advertising and sale of foods represented as a treatment, preventative, or cure for specified diseases and health problems is prohibited in Canada. Although immune function is not included among the list of specified disorders, health claims respecting zinc and immune function on food labels would likely result in the foods being classified as drugs in Canada by virtue of the definition for "drug" in the Canadian law.

These comments are essentially identical to a comment submitted by the Canadian Government in response to FDA's notice requesting scientific data or information on this topic, which published in the **Federal Register** of March 28, 1991 (56 FR 12932). In its proposed rule (56 FR 60652), FDA did not propose to authorize health claims for zinc and immune function on food labels. Thus, no change in the proposed rule is appropriate in response to this comment.

III. Conclusion

FDA reviewed the scientific data in conformity with the requirements of the 1990 amendments, as well as comments received regarding the proposed rule that published in the **Federal Register** of November 27, 1991 (56 FR 60652), and concluded that there is not a sufficient basis to support the use of health claims relating to the topic of zinc and immune function in the elderly.

The agency's examination of publicly available evidence found that, although it is well accepted that adequate dietary zinc is essential for normal immune function, a specific protective role of zinc supplementation of the elderly population has not been demonstrated. Although some small early clinical studies suggested such a relationship, these results were not substantiated in subsequent research using better study designs and larger samples. Therefore, there is no evidence that immune function in healthy persons can be enhanced by zinc supplementation. Zinc is considered to be relatively nontoxic, particularly if taken orally. However, adverse effects, which include impaired immune function, are known to occur with zinc intake in excess of Recommended Dietary Allowances. Thus, FDA has concluded that the publicly available data on the role of zinc in immune system function do not provide a sufficient scientific basis from which to conclude that immune function in the general elderly U.S. population can be improved by zinc supplementation. Moreover, based on the totality of this evidence, there is not significant scientific agreement among qualified experts that a health claim for zinc and immune function in the elderly is supported by the evidence.

IV. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

V. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354 , FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), and along with the food labeling proposals, the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that, although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.71 is amended by adding new paragraph (e) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(e) Zinc and immune function in the elderly.

Dated: October 23, 1992.

[Docket No. 91N–0094]

RIN 0905–AB67

Food Labeling: Health Claims; Calcium and Osteoporosis

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision to authorize the use on the label and labeling of foods of health claims relating to an association between adequate calcium intake and osteoporosis. These rules are issued in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims and are developed in accordance with the general requirements in the health claims rule published elsewhere in this issue of the **Federal Register**. The agency has concluded that, based on the totality of the scientific evidence, there is significant scientific evidence and agreement among qualified experts that maintaining a diet adequate in calcium has a significant impact on bone health particularly during the critical bone forming years and after menopause and may help to reduce the risk of osteoporosis. The agency has therefore concluded that claims on foods relating the calcium content to a reduced risk of osteoporosis in susceptible populations are justified.

EFFECTIVE DATE: May 8, 1993.

FOR FURTHER INFORMATION CONTACT: Mona S. Calvo, Center for Food Safety and Applied Nutrition (HFF–265), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202–205–5434.

SUPPLEMENTARY INFORMATION:

I. Background

In the Federal Register of November 27, 1991 (56 FR 60689), the agency proposed to authorize the use on foods, including dietary supplements, of health claims relating to the association between calcium and risk of osteoporosis. The proposed rule was issued in response to provisions of the 1990 amendments (Pub. L. 101–535) that bear on health claims and in accordance with the proposed general requirements for health claims for food (56 FR 60537). With respect to health claims, the 1990 amendments amend the Federal Food, Drug, and Cosmetic Act (the act) by adding a new provision (section 403(r)(1)(B) (21 U.S.C. 343(r)(1)(B)) that provides that a product is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition unless the claim is made in accordance with section 403(r)(3) or (r)(5)(D) of the act.

Section 3(b)(1)(A) of the 1990 amendments specifically requires that the agency determine whether 10 nutrient/disease relationships meet the requirements of the section 403(r)(3) or (r)(5)(D) of the act. The relationship of calcium and osteoporosis was one of these areas. FDA published a notice in the **Federal Register** of March 28, 1991 (56 FR 12932), requesting scientific data and information on the 10 specific topic areas identified. Relevant scientific studies and data received in response to this request were considered as part of the agency's review of the scientific literature on calcium and osteoporosis and were included in the proposed rule (56 FR 60689). Because of time constraints, FDA addressed in that proposal only those comments submitted in response to the March 28,1991, notice that were in the form of scientific data. Comments of a more specific nature were not responded to at that time and are included among the comments responded to below.

Provisions of the proposed rule included qualifying and disqualifying criteria for the purpose of identifying foods eligible to bear a health claim. The proposal also specified mandatory content and label information for health claims statements and provided a model health claim and consumer summary statement. FDA also discussed potential safety issues relating to overfortification or oversupplementation with calcium. FDA requested written comments on the proposed rule, including comments on the issue of how to assess calcium bioavailability in products (conventional foods and supplements) to justify their eligibility to bear a health claim. Moreover, to ensure that calcium and osteoporosis claims will not mislead those individuals within the population for whom relatively higher calcium intake over a lifetime offers no apparent benefit to their bone health, FDA proposed that the subpopulations clearly at risk be identified on the label and solicited comments on how best to convey this information.

II. Summary of Comments and the Agency's Responses

In response to the proposed rule, the agency received more than 100 letters, each containing one or more comments, from consumers, consumer organizations, health care professionals, professional organizations, State and local governments, foreign governments, trade associations, and industry. In addition to these comments, the agency also considered statements made in a public hearing held on January 30 and 31, 1992 (57 FR 239, January 3, 1992) on a number of food labeling issues, including the proposed requirements for health claims. Some of the comments agreed with one or more provisions of the proposed rules without providing grounds for support other than those provided by FDA in the preamble to the proposal. Other comments disagreed with one or more provisions of the proposed rule without providing specific grounds for the disagreement. A few comments addressed issues outside of the scope of the regulations. Most of the comments provided specific support for their positions on the proposed regulations. The agency has summarized and addressed the relevant issues raised in all comments in the sections of this document that follow.

Before issuing the proposal, FDA contracted with the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology to evaluate independently the scientific literature on dietary calcium and osteoporosis. The preliminary draft of the LSRO report, "Calcium and Osteoporosis" (Ref. 13), was one of the authoritative documents reviewed by FDA in developing its proposal. After the proposal was issued, LSRO completed its evaluation of the scientific literature and submitted its final report in February 1992. The agency placed a copy of the final report in the administrative file (Ref. 138), and has considered the report as a comment on the proposal.

A. Validity Issues

1. No comments disputed FDA's tentative conclusion that a lifetime of adequate calcium intake is important for maintenance of bone health and may help reduce the risk of osteoporosis, particularly for individuals at greatest risk. Most comments supported the agency's position.

The LSRO report (Ref. 138) concluded that "the weight of the evidence supports the hypothesized relationship between calcium intake and bone health as expressed both in increased bone mass and in reduced fracture risk." According to LSRO, "the focus of calcium as a nutrient related to osteoporosis lies in its importance both for achieving genetically programmed bone mass during about the first 30 to 35 years of life and in maintaining that

bone during the remaining years of life." The report stressed that osteoporosis is a multifactorial disorder, and that inadequate calcium intake is only one of several interacting factors that determine whether low-trauma fracture will occur. The report also noted that "the data concerning level of [calcium] intake required for bone health can be safely generalized only to Caucasian females."

FDA acknowledges the significant agreement on this matter and reconfirms its position that adequate calcium intake is important for maintenance of bone health and may help reduce the risk of osteoporosis, particularly for individuals at greatest risk. FDA notes that the LSRO report is consistent with required health claim statements about the mechanism by which calcium works (proposed § 101.72(d)(3), finalized at § 101.72(c)(2)(i)(C)) and the population at greatest risk (§ 101.72(c)(2)(i)(B)). As discussed in the proposal (56 FR at 60698), FDA agrees that the general population is not at significant risk of developing osteoporosis. For example, despite their generally lower calcium intake, data show that African Americans have higher bone mass at maturity and a very low incidence of osteoporosis-related bone fracture.

B. Advisability of Permitting Claims

2. One comment asserted that health claims pertaining to calcium and osteoporosis should not be permitted because (1) the target population for the claim is too small, and (2) older people with the condition may be misled into thinking the rate of bone loss will be slowed or reversed with increased calcium consumption.

FDA disagrees with this comment, which provided no support for its assertions. First, a large number of American women are at risk of developing osteoporosis (Ref. 18). Further, many of the elderly have low bone mass, and they continue to lose bone mass with further aging. These individuals will clearly benefit from information about how they may reduce their risk of the disease.

Secondly, as explained fully in the preamble of the proposal (56 FR at 60689), adequate calcium intake does help to slow the rate of bone loss in the elderly. Thus, while under § 101.72, claims may not imply that adequate calcium intake will reverse bone loss, under § 101.72 (c)(2)(i)(C), when reference is made to persons with a family history of the disease, menopausal women, and elderly men and women, the claim may state that adequate calcium intake is linked to reduced risk of osteoporosis through the mechanism of slowing the rate of bone loss. For these reasons, FDA disagrees that permitting claims to advise of the reduction in the rate of bone loss will mislead the elderly.

3. A few comments argued that a health claim should not be allowed because delay of the onset of osteoporotic fracture is not exclusively associated with adequate calcium intake. One of the comments justified this assertion by stating that many essential nutrients in addition to calcium, such as magnesium, copper, zinc, fluoride, and vitamins A, D, K, and C, are needed for normal bone growth and development.

FDA recognizes that many nutrients are essential for normal bone growth and development. However, FDA disagrees that this fact should preclude the agency from permitting a health claim pertaining to calcium and osteoporosis. The requirement in § 101.72(c)(2)(i)(A) that claims advise consumers of the importance of healthful diets is intended to alert consumers to the need to consume essential nutrients in addition to calcium. As the agency explained fully in the proposal (56 FR at 60689), national food intake surveys (Refs. 35, 54, and 105) provide evidence identifying calcium from dietary sources as a problem nutrient in a subpopulation at risk for osteoporosis, namely women between 11 and 35 years of age. Furthermore, FDA has concluded that based on the totality of the scientific evidence, there is significant scientific agreement among qualified experts that the evidence overwhelmingly supports the significance of calcium in maintaining bone health. Thus, FDA believes that the population at greatest risk of osteoporotic fracture in later life should be advised through food labeling of the benefits of adequate calcium intake.

C. Clarity of Provisions

4. A number of comments on the proposed rule on general requirements for health claims (November 27, 1991, 56 FR 60537) suggested that FDA revise provisions of all health claims rules to be more understandable.

FDA agrees that its regulations should be understandable. FDA has therefore made several nonsubstantive revisions in § 101.72 for the sake of clarity. For example, the provisions of the regulation have been grouped into general and specific requirements. The general requirements reference other regulations containing nutrition labeling requirements. The specific requirements are separated into requirements pertaining to the food and those pertaining to the claim. Finally, the model health claims have been simplified.

D. Qualifying Levels

5. A few comments addressed the issue of an appropriate qualifying level for calcium in a food. All of the comments strongly supported the requirement that a food bearing a calcium-osteoporosis claim be "high" in calcium (i.e., contain a minimum of 20 percent of the reference daily intake (RDI)). A number of the comments, however, asserted that the RDI was being set too low. One comment stated that the proposed RDI for calcium (900 mg) was an inadequate intake guideline for those individuals at greatest risk of osteoporosis. Another comment argued that there is substantial evidence that the population-weighted means used to establish the RDI's may seriously understate the nutritional needs of an estimated 52 million Americans.

For reasons explained fully in the preamble of the final rule on Reference Daily Intake and Daily Reference Values, which is published elsewhere in this issue of the Federal Register, FDA has adopted an RDI for calcium of 1,000 mg, the level in current § 101.9(c)(7)(iv). In view of the support for the proposal that only foods "high" in calcium qualify for calcium-osteoporosis claim, the agency has retained this requirement in the final rule in § 101.72(c)(2)(ii)(A) (proposed as § 101.72(c)(2)) with minor editorial revisions. Because the RDI for calcium is 1,000 mg, the reference amount customarily consumed for a food would need to contain at least 200 mg of calcium for it to qualify to bear the authorized calcium/ osteoporosis health claim.

E. Assimilability

All comments on this topic generally supported the concept of a requirement that the calcium content of the product be assimilable (proposed as § 101.72(c)(3) and finalized as § 101.72(c)(2)(ii)(B)). In response to an agency request in the proposal for comments about how to assess calcium assimilability (also referred to as "bioavailability"), a few comments suggested mechanisms to assess calcium bioavailability.

6. Several comments suggested that the agency establish a minimum standard that relates bioavailability to the amount of calcium actually absorbed from food. One comment cited the existence of a recognized data base describing the absorption of naturally occurring supplemental and fortified calcium in foods. However, the comment added that the cited data base

was actually a bibliography of various published articles describing calcium absorption from a variety of food sources. Another comment offered the following suggestion: "FDA should estimate the quantity of calcium in various foods that is rendered unavailable by oxalic acid, phytate, fiber, or other constituents and subtract this unavailable calcium from the amount of available calcium that the food would be expected to supply (which is usually only about half of the reported calcium content of food)." The comment suggested that FDA should not allow health claims on a given food if, after adjustment for oxalate and other constituents, the estimated quantity of "available" calcium is markedly lower than ordinarily expected, given the food reported calcium content. Similarly, another comment proposed the use of the indirect method of calciuric response to a calcium load as a convenient and reliable method of testing calcium absorbability and also proposed a test based on radiocalcium absorption.

FDA acknowledges these useful suggestions but notes that none of the proposed methods assesses calcium utilization. As discussed in the proposal, calcium bioavailability means both absorption and tissue utilization of calcium (56 FR at 60699). Appropriate tests for bioavailability need to include a measurement of the utilization of calcium by bone (calcium retention). A product that contains components that increase the urinary or fecal excretion of calcium or somehow impair the utilization of calcium by bone will not qualify for a calcium-osteoporosis claim. Monitoring only factors that alter absorption, such as the phytate content of a food, as suggested in the comment, would not allow estimation of the effects of factors that promote obligatory calcium loss such as increased urinary loss due to a high sulfate content. Both increased excretion and impaired utilization cause the decreased deposition of calcium in bone.

7. Some comments requested that FDA clarify an acceptable level of "assimilability," such as an acceptable percent bioavailability. The comments asserted that it would be unrealistic to require bioavailability data on all foods bearing a calcium claim, but that such a requirement might be a logical prerequisite for new sources of calcium used to fortify foods. A number of comments suggested that food and supplement manufacturers should bear the burden of proof of the bioavailability of calcium-fortified products and supplements in order to avoid indiscriminate fortification and marketing of poorly bioavailable supplements.

FDA reiterates that a product bearing a calcium-osteoporosis health claim must contain calcium that can be assimilated by the body. As noted in the proposal, it would be misleading to put a health claim for a substance on a food if consumption of that food will not provide the substance (56 FR at 60699). Such a food would be misbranded under section 403 (a) of the act (21 U.S.C. 343(a)). Given that most currently marketed products that are likely to bear a calcium-osteoporosis claim contain bioavailable calcium, FDA does not consider it necessary at this time to set a minimum acceptable level of bioavailability. If a food bearing a calcium osteoporosis claim does not contain calcium in a bioavailable form, the Government can take enforcement under the act against the product or its manufacturer. Calcium sources whose bioavailability has not been demonstrated would be at risk for such enforcement action.

There are sufficient scientific data in published literature to support the bioavailability of many sources of calcium in current use. However, instances may develop in which the bioavailability of the calcium source has not been shown, including the use of new fortificants or food products in which the combination of the component nutrients raises concerns about the assimilability of calcium from the product (e.g., a new bread rich in a novel high phytate fiber source and fortified with calcium).

As discussed in the previous comment, there are various ways of testing for bioavailability. FDA considers human or growing animal models to provide the most accurate assessments. One approach would involve collection of human data from calcium balance studies using stable isotopes or radioisotopes as evidence of reasonable or adequate bioavailability (assimilability), as well as evidence from well-controlled calcium supplementation or dietary intervention studies that measure calcium absorption and bone mass or density change over time. An appropriate standard reference would be calcium carbonate or milk.

FDA recognizes that establishing calcium retention in humans is a difficult and costly procedure. Another approach would use a growing animal model (rat) to demonstrate calcium retention in bone. Use of the growing rat model offers ease of bone mass or mineral content assessment, and, unlike human subjects, rats show limited between-subject variation in calcium absorption. There are a number of suitable studies in the literature that could serve as models and the basis for a study design (e.g., Refs. 139 through 141). The common end-measures shared by these animal studies include measures of apparent calcium absorption and determination of calcium content of bone, either directly by bone ashing and mineral analyses (Refs. 139 and 140) or indirectly by densitometric or histomorphometric methods (Ref. 141).

8. A number of comments proposed that superiority claims regarding the bioavailability or absorbability of calcium in a food or supplement compared to a reference food or supplement be permitted. One comment proposed milk as an ideal reference food against which to make the proposed comparisons and suggested the use of human bioavailability tests to provide evidence in support of superiority claims. Several comments suggested that a statistically significant difference in calcium absorption between two products using the proposed techniques should provide the basis for a superior absorbability comparative claim.

FDA advises that it is not appropriate to permit requested superiority claims under the provisions of the 1990 amendments that govern health claims. To the extent that the 1990 amendments provide for comparative claims, it is only with respect to claims that charaterize the level of a nutrient (section 403 (r)(1)(A) of the act). Regulations governing nutrient content claims, published elsewhere in this issue of the **Federal Register**, do not provide for superiority claims based on bioavailability. However, under § 10.30, an interested party can petition the agency to provide for superiority claims based on bioavailability. In considering such a petition, the agency would be concerned about ensuring that superiority claims are valid and nutritionally meaningful.

F. Disintegration and Dissolution of Calcium Supplements

9. The majority of comments concerned with the proposed requirement that calcium supplements meet the U.S. Pharmacopeia (U.S.P.) standards for disintegration and dissolution of calcium supplements (in proposed § 101.72(c)(4)) fully supported this aspect of the proposed regulation. The LSRO report strongly supported the proposed requirement noting that while the chemical form or solubility of the supplement makes little difference, the physical form of the salt and formulation of the tablet are critical. The comment stressed that "tablets so poorly formulated that they fail to disintegrate

under simulated gastric conditions appear to be widely distributed in the U.S. market." A public health advocacy group further suggested that since the U.S.P. is currently updating its standards for dietary supplements, the revised standards may include additional measures that FDA should adopt in the future. Two comments opposed this requirement. One argued that "the United States Pharmacopeia standards are not appropriately complete enough to be an exclusive condition for a product's health claim eligibility." The comment asserted that the U.S.P.'s are in vitro standards (meaning conducted in a test tube) and might not reflect human bioavailability of an individual calcium supplement, and they should therefore only establish a disqualifying presumption that would be rebuttable by the submission of human data supporting the product's bioavailability. Another comment emphasized the lack of justification for this testing, the inability to conduct all the tests since some of the calcium salts identified as safe for use as calcium supplements are not subject to U.S.P. dissolution requirements (calcium sulfate, and calcium oxide), the lack of fairness in that foods are not held to these criteria, the inappropriate application of drug standards set forth in the U.S.P. monographs to supplements, the "questionable expertise" of the U.S.P. convention members to judge nutritional property of compounds, and finally the lack of basis to require these standards in order to qualify for a health claim.

FDA has carefully considered these comments and agrees with several points. FDA agrees that disintegration and dissolution testing methods used to screen calcium supplements for bioavailability are imperfect, because these in vitro tests do not adequately mimic the physiologic environment of the human stomach, and U.S.P. standards are not available for all calcium-containing compounds. However, the agency considers the U.S.P. standards to provide sufficient assurance of dissolution and disintegration for those products where U.S.P. standards exist. A supplement that does not dissolve and disintegrate clearly does not provide calcium in an assimilable form and thus, a claim for such a supplement would be misleading because the supplement would not provide the nutrient that is the subject of the claim. Calcium supplements not in conventional food form can be formulated in a manner that prevents rapid dissociation and disintegration in the stomach, preventing assimilation. This unique aspect justifies the requirement in § 101.72(c)(2)(ii)(C) for supplements.

However, when U.S.P. standards do not exist, the agency recognizes, as pointed out by one comment, the need for an alternative method of establishing the bioavailability of supplements under the conditions of use stated on the product label. Demonstration of acceptable bioavailability in human or animal studies when conducted under the conditions of use stated on the product label (i.e, fed as an intact tablet, not crushed) would fulfill the requirement. Section 101.72(c)(2)(ii)(C) has been revised to require that dietary supplements meet the U.S.P. standards for disintegration and dissolution, except that dietary supplements for which no applicable U.S.P. standards exist shall exhibit appropriate assimilability under conditions of use stated on the product label. In order for a dietary supplement to bear the authorized calcium osteoporosis health claim, it must comply with all provisions of this final regulation.

G. Phosphorus Content

For reasons explained fully in the preamble of the proposal (56 FR 60689 at 60699 to 60700), FDA proposed that high levels of phosphorus (naturally occurring or added) in conventional foods or supplements that result in calcium to phosphorus ratios lower than 1:1 will disqualify the product from bearing a calcium/ osteoporosis health claim. FDA's tentative decision to place a limit on the amount of phosphorus that a food could have to be eligible to bear a claim was based on the ubiquitous distribution of this mineral in the food supply, the low ratio of calcium to phosphorus that typifies current intake patterns, and current evidence demonstrating that high levels of dietary phosphorus coupled with low dietary calcium adversely influence hormonal factors that regulate calcium and bone metabolism (Refs. 17, 21, 29, 32, 46, 93, 114, and 116). Many of the comments addressing this issue strongly supported the proposed phosphorus provision because of the reasons given by FDA in the proposal.

10. One comment questioned the need for any requirement that the phosphorus content not exceed the calcium content, asserting that "any reasonable fortified or enriched product will meet this condition."

The agency believes that it is incorrect to assume that all enriched, fortified, or modified products will contain more calcium than phosphorus, or even that products traditionally known to be rich sources of calcium will have lower levels of phosphorus than calcium. For example, a recent article (Ref. 142) on the reduction of fat in a newly developed processed cheese showed how processing techniques used to lower fat resulted in a calcium to phosphorus ratio lower than one to one. Some products naturally rich in phosphorus cannot meet this condition even after calcium fortification, and some products that are traditionally recognized as calcium rich foods, such as puddings, are now available in convenient instant versions in which the added phosphorus content far exceeds the calcium content. Therefore, FDA concludes that this comment does not provide a basis not to adopt a level of phosphorus that, if found in a food, would render the calcium osteoporosis claim misleading.

11. Several comments were in strong opposition to the requirement that a product not contain more phosphorus than calcium on a per weight basis. One comment contended that FDA relied on erroneous information relative to the consumption levels of dietary phosphorus supplied by food additives. The comment included data indicating little change in the estimated daily consumption of phosphorus from food additives from 1980 to 1990, based on the International Food Additives Council's estimated disappearance of food grade phosphorus in the United States. According to these data, the average per capita phosphorus consumption from food additives increased from 9.5 to more than 11 percent of the acceptable daily intake of phosphorus from 1980 to 1990.

FDA's statement in the proposal that phosphorus intake may be understated by as much as 15 to 20 percent due to phosphorus supplied by numerous additives was apparently misinterpreted by these comments. The agency did not intend to imply that phosphorus-containing food additive consumption had increased 15 to 20 percent. Rather, the agency was relying on the finding of Oenning et al. (Ref. 106), who demonstrated that nutrient estimates calculated from food intake records using current nutrient composition data bases underestimated phosphorus intake when compared to direct chemical analysis of the food from the dietary record. The underestimation of phosphorus content demonstrated in this study apparently was due to errors in the nutrient data bases, which have not kept abreast of changes in manufacturing techniques and in the use of phosphorus-containing food additives. FDA made this point to emphasize that currently in the United States, total phosphorus intake greatly

exceeds that of calcium, and that the levels may be even higher than surveys suggest because of flaws in the nutrient composition data bases used in these surveys.

The agency disagrees with the comment and interprets data presented by the comment as evidence of an important increase in phosphate food additive use over the last decade. These data indicate that estimated per capita daily consumption of phosphorus from food additives reported by the International Food Additive Council for 1990 was 470 milligrams (mg) phosphorus per day per capita as compared to an estimated 400 mg of phosphorus per day per capita for 1980, or approximately a 17 percent increase in per capita use over the last decade. Thus, more than one line of evidence points to the fact that the consumption of phosphorus-containing additives is on the rise and contributes to the high phosphorus intake observed in the United States population.

12. Another comment strongly opposed the proposed limit on phosphorus content for a number of reasons. The comment asserted that any health claim disqualifier must meet the same conditions as the claim itself, such as unanimous agreement among experts, and that no studies to date have demonstrated an adverse effect of excess phosphorus on bone in man or in monkeys or in calcium balance studies. This comment also asserted that there is a controversy over the effect of high phosphorus on calcium absorption and pointed to the fact that no single food contributes to the high phosphorus intake and to the remote possibility that reduction of phosphorus intake from one food will reduce total phosphorus intake.

The agency does not agree that any of these points warrants modification of the limit on phosphorus content in § 101.72(c)(2)(ii)(D). The limit on phosphorus is not a "disqualifying level" as that term is defined based on section 403(r)(3)(A)(ii) of the act. FDA is not limiting the phosphorus content because of its effect on the risk of a diet-related disease or health-related condition. FDA may have contributed to confusion in this regard by stating in the proposal that the level of phosphorus would disqualify a product from bearing a claim (56 FR at 60699). FDA is limiting the amount of phosphorus under the authority of section 403(a) of the act. As explained above, high levels of phosphorus when calcium intakes is low, would impair the utilization of calcium by bone. Thus, the presence of a calcium/osteoporosis claim on a food that does not have an appropriate calcium-phosphorus ratio would be misleading, because it would not be possible to get the full benefits of calcium from such a food.

In response to the criticism that no studies have demonstrated direct adverse effects of excess phosphorus on bone in humans or primate models, the agency points out that evidence in humans demonstrates that high levels of dietary phosphorus coupled with low dietary calcium intake adversely influence hormonal factors that regulate calcium and bone metabolism (Refs. 17, 21, 29, 32, 46, 93, 114, and 116). These changes were consistent with those observed in a variety of animal models where the hormonal changes were shown to induce bone resorption and ultimately bone loss (Ref. 46). The agency is particularly concerned about teens and young adults who typically consume more phosphorus than calcium (Ref. 105) and for whom such diets have recently been shown to produce changes in serum calcium and bone-regulating hormones that may adversely affect attainment of peak bone mass (Ref. 32). The health claim is an effective means of alerting this vulnerable population to foods that have the desired ratio of these two nutrients. Therefore the agency does not agree with the comment's suggestion that the limit on phosphorus content be dropped.

The agency does not disagree with the other assertions made in this comment. These points are minor and, given that health claims are authorized in the context of the total daily diet, not particularly relevant. The agency did not assert that excess phosphorus impaired calcium absorption and has maintained that phosphorus is ubiquitously distributed in the food supply. Given the effects of phosphorus on hormonal factors that regulate calcium and bone metabolism, FDA concludes that the limit on phosphorus content for a food that bears a calcium/osteoporosis claim is appropriate.

H. No Quantification of Reduction in Risk

13. One comment urged FDA to avoid any possible misinterpretation and potential abuse of the calcium/osteoporosis regulation by specifying in the regulation that "the claim shall not convey the misconception that dietary calcium intake can cure osteoporosis." The comment included examples of labels of dietary supplements found in health food stores.

The agency agrees with the comment's concern but remains confident that the claims being authorized will not mislead consumers into believing that calcium cures osteoporosis. This regulation authorize a health claim that relates calcium intake to a reduction in the risk of osteoporosis. A statement that calciun cures osteoporosis would constitute a drug claim under section 201(g)(1)(B) of the act (21 U.S.C. 321(g)(1)(B)), and a product bearing such a claim would be subject to regulation as a drug. In addition, § 101.72(c)(2)(i)(D) bars health claims on calcium and osteoporosis from attributing any degree of reduction in risk of osteoporosis to maintaining an adequate calcium intake throughout life

I. Limitations of Benefit to Bone Health

14. Several comments opposed the upper-limit-of-benefit statement proposed in § 101.72(d)(5), saying that this statement was an effort to limit the potency of supplements. A number of comments supported the statement but required that it be qualified. One comment requested that the statement only be placed on products in which the calcium level is greater than 50 percent of the originally proposed RDI of 900 mg or 450 mg of calcium (presumably per serving or per recommended daily dose). This comment reasoned that for products with lower levels of calcium, an unreasonable number of servings of food would need to be consumed to exceed 200 percent of the RDI, and thus the statement was not necessary.

FDA does not agree with the assertion that it is seeking to limit the potency of supplements. This regulation relates only to the type of health claim that a product may bear. It ensures that a material fact about the consequences of consumption of more than a specified level of calcium is presented as part of the claim. FDA agrees in principle with the suggested change in proposed § 101.72(d)(5) and believes that this modification may help curb overfortification. The agency has therefore added the following language to the proposed provision redesignated as § 101.72(c)(2)(i)(E)): "This requirement does not apply to foods that contain less than 40 percent of the recommended daily intake of 1,000 mg of calcium per day or 400 mg of calcium per reference amount customarily consumed or per total daily recommended supplement intake."

J. Safety

15. A public health advocacy association suggested that FDA require labels on high dose calcium supplements to disclose that high calcium intakes may increase the risk of kidney stones in susceptible people. The comment argued that levels greater than 1,000 to 2,500 mg calcium per day

may pose a risk to people with a history of kidney stones, and that, therefore, labels on supplements that contain 500 mg or more of calcium should inform consumers of this risk.

The agency does not agree that a warning is needed in addition to the statement on total dietary intakes greater than 200 percent of the RDI. Section § 101.72(c)(2)(i)(B) requires that the health claim identify the populations at greatest risk of osteoporosis, namely caucasian and Asian women in their bone forming years. Kidney stones are more prevalent in men than women. (With respect to calcium oxalate or mixed calcium stones, affected males outnumber affected females by three or four to one in the U.S. population (Ref. 143).) Thus, while men are at greater risk of the adverse affects of excess calcium intake due to their greater susceptibility to kidney stone formation, they are not at greater risk for osteoporosis and will not be targeted by the calcium-osteoporosis health claim. Consequently, there is no reason to expect that men will increase their consumption of calcium in response to the claim. Therefore, FDA concludes that the regulations offer sufficient protection without the proposed warning.

K. Consumer Summary

16. The comments specific to the proposed consumer summary were generally supportive, and some considered consumer summaries necessary to put any health claim into perspective as related to total diet. The use of the consumer summary on package inserts was suggested by several groups. Several comments suggested various ways to shorten the summary, while others suggested additional information to incorporate. One comment strongly opposed the consumer summary, stating that in light of the detailed, balanced information provided in the model claims, summaries are redundant, costly, and inconvenient to the manufacturer.

As discussed in the final rule on general requirements for health claims, consumer summaries are not required, although their use remains an option. For this reason, FDA has not included the proposed consumer summary on calcium and osteoporosis in this final rule.

L. Regulatory History of Calcium-containing Food Additive Use

The agency advised that, in order for calcium-containing food ingredients in conventional foods or calcium supplement products to be considered eligible to bear the authorized calcium/ osteoporosis health claim, they must meet the requirements in § 101.14, which include that they have been shown to FDA's satisfaction to be safe and lawful under the applicable safety provisions of the act (56 FR at 60699). Safety and lawfulness can be demonstrated in a number of ways, including through a showing that a food is generally recognized as safe (GRAS), affirmed as GRAS by FDA, listed in the food additive regulations, or subject to a prior sanction. Of the 36 or more calcium-containing ingredients identified by the agency as currently in use (Ref. 33), FDA advised that only the following 10 compounds had been demonstrated to be safe and lawful for use in a dietary supplement or as a nutrient supplement: calcium carbonate, calcium citrate, calcium glycerophosphate, calcium oxide, calcium pantothenate, calcium phosphate, calcium pyrophosphate, calcium chloride, calcium lactate, and calcium sulfate (56 FR at 60691).

17. One comment pointed out that the agency failed to include calcium ascorbate in this list of 10 compounds. The comment included also submitted an April 1989 letter from FDA stating the agency's lack of objection to the use of calcium ascorbate in dietary supplements. Another comment sought the addition of calcium hydroxide to the list of 10 calcium compounds discussed above, contending that "since calcium oxide is permitted and calcium hydroxide is simply the hydrate of the oxide formed on contact with water," calcium hydroxide should be included in the list.

As stated above, only 10 compounds have been demonstrated to FDA's satisfaction to be safe and lawful for use in a dietary supplement or as a nutrient supplement bearing a calcium/ osteoporosis health claim. In Ref. 33 of the proposal, the agency identified the calcium-containing ingredients currently in use, their functions, conditions of use, and limits on the levels at which they can be added to food. Only those ingredients with stated use as a nutrient supplement or in a dietary supplement are considered eligible for a health claim. Calcium ascorbate appears only under 21 CFR 182.3189 (Ref. 33) for use as a chemical preservative. Thus, FDA's failure to list it was not inadvertent. Calcium ascorbate is not eligible at this time for consideration for a health claim; however, a petition may be filed requesting a safety review for a new use of calcium ascorbate. Based on the outcome of this petition and review, calcium ascorbate may be considered eligible for a calcium/ osteoporosis health claim.

The agency declines to add calcium hydroxide to the list of 10 calcium-containing compounds that have been demonstrated to be safe and lawful for use in a dietary or nutrient supplement. In the list, FDA identified those ingredients with stated uses as a nutrient or dietary supplement, thus avoiding the use of potentially poorly suited or potentially harmful compounds. FDA's failure to include calcium hydroxide on the list does not imply that the agency considers the use of this substance to be unsafe for use as a calcium supplement, but rather reflects that it has not been demonstrated safe and lawful for this use. Manufacturers who would like to be abel to make a calcium/ osteoporosis health claim based on the presence of calcium hydroxide in their product should submit an appropriate petition to FDA.

M. Food Fortification

18. A public health and nutrition association expressed concern that manufacturers seeking a calcium/ osteoporosis health claim will fortify products of low nutritional value that do not naturally contain calcium. The comment recommended that FDA consider setting standards for the amount of fortification that is allowed and also suggested that FDA determine which products can be fortified.

Although the agency understands the concern expressed in the comment, the full implementation of these suggestions is beyond the scope of this rulemaking. The agency advises that fortification of foods to qualify for a health claim must comply with the final rule on general requirements for health claims published elsewhere in this issue of the Federal Register.

N. Nutrition Claims

19. One comment argued that claims relating to a nutrient's effect on the structure or function of the body are not health claims but nutrition claims. The comment suggested amending the proposed regulations to clarify the distinction between nutrition and health claims. In the event that FDA's rejected this proposal, the comment asked that the agency acknowledge that the relationship between calcium and bone health is a nutrition claim that is substantiated in the proposed calcium/ osteoporosis health claim regulation.

FDA rejects these suggestions. The distinction between nutritional guidance and health claims is discussed in the final rule on general requirements for health claims. The claim authorized

..nder this regulation re.ating calcium and osteoporosis is a health claim because it characterizes the relationship of a nutrient (calcium) to a disease or health-related condition (osteoporosis). A claim relating calcium to bone health would have to be evaluated on its own merits. Such a claim might be considered an implied health claim, rather than merely a statement about a food's effect on the structure or function of the body, and, if so, it would be subject to regulation under section 403(r) of the act.

O. Model Claim

20. Many comments discussed the length of the model health claim and its required components. Common to all comments was the complaint that the model message was too wordy. Comments were almost equally split between those supporting and those opposing the proposed model message. Supporting comments praised specific aspects of the model claim such as disclosure of other risk factors; the likely upper limit of beneficial calcium intakes; reflection of other factors that contribute to osteoporosis risk such as age, race, and sex; inclusion of the need for exercise; and disclosure of the mechanisms through which calcium may reduce the risk of osteoporosis. Opposing comments emphasized the burdensome length of the model claim. One comment stated that the length of the claim would not allow it to be translated into multiple languages on the label. Many comments requested that FDA remove the requirements that populations at special risk of osteoporosis and nondietary factors that can help prevent osteoporosis be identified. Several comments suggested that the length of the claim will limit its effectiveness and curtail manufacturers' incentives to make claims. An association of national advertisers asserted that no diet and disease relationship can be explained completely in one paragraph.

The agency agrees that the proposed model health claim was too long. However, as discussed in the proposal and elsewhere in this final rule, certain information is needed in the health claim in order for it to be truthful and not misleading to segments of the population that are not at high risk of developing osteoporosis or for whom no link between calcium and osteoporosis has been established. FDA notes that the proposed model claim contained optional as well as required information, and the example has been rewritten to demonstrate that all required information can be included in a model claim of less than 35 words: "Regular exercise and eating a healthful diet with enough calcium helps teen and young adult white and Asian women maintain good bone health and may reduce their high risk of osteoporosis later in life." Foods that contain less than 40 percent of the recommended daily intake of 1,000 mg of calcium per day (400 mg calcium) per reference amount customarily consumed or per total daily recommended supplement intake may bear this claim. Other foods that contain higher levels of calcium must also carry an additional statement (see § 101.72(c)(2)(i)(E)).

Throughout FDA's responses to the comments in this preamble, the agency has presented various reasons that strongly support maintaining the requirements that make the claim lengthy. These points include the need not to mislead the public in thinking everyone is at risk for this disease, the need to identify those at greatest risk and thus to help individuals who are not at risk but who are susceptible to the adverse effects of oversupplementation with calcium avoid any problems, and the need to target the age group for which adequate calcium intake may have the greatest benefit for bone health and delayed risk of osteoporotic fracture.

P. Other Issues

21. One comment contended that FDA should permit health claims on OTC antacid products containing only calcium carbonate. Responding to a discussion on dual labeling in the proposal on general requirements for health claims (56 FR 60537), the comment asserted that FDA's objection to OTC drugs bearing health claims is not appropriate in the case of calcium-based antacids, because such products have been labeled for years with both food and drug labeling.

FDA has addressed the issues raised by this comment in the final rule on general requirements for health claims, published elsewhere in this issue of the **Federal Register**.

22. Another comment urged that the regulation require disclosure about the relationship between calcium and protein and suggested disqualifying high protein products based on the effect of dietary protein on the urinary loss of calcium, which affects bone health.

As mentioned in the preamble of the proposal (56 FR at 60699), the agency recognizes that high levels of dietary protein typically found in the American diet have been shown to increase the obligatory loss of calcium, i.e., the amount of calcium that the body must lose daily. The agency, however, did not propose to disqualify high-protein products from bearing a calcium/osteoporosis claim or to disclose the effect of high protein intake on calcium retention on the label. Like calcium, protein is not ubiquitously distributed in our food supply and is richest in specific food sources (Refs. 27 and 110). Relatively few foods are sources of calcium and protein, forcing consumers to be selective to meet the nutritional needs for both calcium and protein. Some protein rich foods, such as lowfat milk or lowfat milk products, contribute more than half the calcium and protein intake of some individuals, notably children. It would be misleading to the public not to allow an important food such as lowfat milk to have a calcium/osteoporosis claim due to its high levels of protein. To disqualify a product that is both rich in calcium and protein, and that would not be disqualified because of its fat, saturated fat, cholesterol, or sodium levels, because of its protein content, would effectively prevent several major food sources of calcium from bearing a claim.

Several other considerations reinforce the agency's position that protein content should not be a basis for disqualification from bearing a calcium/osteoporosis claim or for a disclosure statement. The scientific evidence demonstrating a persistent increase in the urinary loss of calcium when high protein intakes are sustained for months is weak and controversial. In addition, different protein sources have been shown to elicit varying degrees of calciuria (increased loss of calcium in urine), thus making it incorrect for the agency to consider all dietary protein sources equally potent in their calciuric effect. Moreover, no clear evidence exists demonstrating that high protein intake alters any of the hormones that control bone formation and resorption, or that high protein intake impairs bone mineralization.

FDA is making several minor changes in the regulation to improve its readibility and to make it consistent with other regulations that FDA is adopting that authorize health claims. The most significant of these changes is the fact that FDA is adding to the paragraph on optional information a provision that will allow the declaration as part of the claim of the number of people who are affected by osteoporous (§ 101.72(d)(2)). This change makes § 101.72 consistent with the other regulations in Subpart E. Therefore, FDA is rejecting the comment's suggestion to require a statement about the relationship between calcium and protein or to establish a level of protein

that would disqualify a product from bearing a calcium/osteoporosis claim. The agency concludes that a product high in protein can still be an important source of calcium and that it cannot conclude that a claim would be misleading if it fails to reveal the relationship between calcium and protein.

III. Review of Scientific Evidence

FDA updated its review of the scientific literature by examining articles published since the proposed rule was issued. FDA's evaluation of recent human studies meeting the criteria outlined in the proposal (56 FR at 60693) is presented in Table 1 (Refs. 144 through 150). In addition, FDA also considered several review articles that were published since the proposal (Refs. 151 through 156). FDA sought to answer the same questions posed in the proposed rule.

First, do any of the recent studies present evidence documenting the role of calcium in achieving peak bone mass? A cross-sectional study examining spinal bone density in Caucasian girls 8 to 18 years of age demonstrated that calcium intake may be a major factor in achieving peak adult bone density (Ref. 148). Chan et al. (Ref. 145) also demonstrated higher bone mineral content in Caucasian boys and girls consuming greater than 1,000 mg of calcium per day. In this study 70 percent of the subjects younger than 11 years consumed at least their RDA of 800 mg of calcium per day, while 63 percent of the subjects older than 11 consumed less than their RDA of 1,200 mg per day. After adjustment for phosphorus and protein intake, multivariate analyses showed only calcium intake was related to bone mineral status of the children in this study. Thus, the most recent data, although not definitive, continue to strongly support the link between adequate calcium intake and optimal peak bone mass.

The second question asked in reviewing these studies is whether added calcium or high calcium intake reduces the risk of fracture or slows the rate of bone loss in younger or older subjects. Andon et al. (Ref. 144) showed, in a cross-sectional study, that Caucasian postmenopausal women consuming less than 600 mg calcium per day had significantly lower spinal bone mineral densities than women with higher calcium intakes. Because individuals who malabsorb lactose normally avoid dairy products, Wheadon et al. (Ref. 150) assessed lactose absorption and dietary calcium intake in elderly women with and without hip fractures and in young women. While 60 percent of the women with hip fractures were lactose malabsorbers, dietary calcium intakes did not differ significantly among the three groups. However, the authors cautioned against putting too much weight on the findings of the small study (n=31) since the aversion to milk and milk products ascribed to lactose intolerance may be shown to decrease calcium intake in a larger population.

As discussed in the earlier literature review, the responsiveness of postmenopausal women to calcium supplementation depends largely on their menopausal age. Calcium supplementation had no effect on spinal bone density early in menopause, but for women late in menopause, the rate of bone loss could be significantly reduced with calcium supplementation, if initial habitual calcium intakes were low (Refs. 47 and 151). Three recent prospective intervention studies (Refs. 146, 147, and 149) shed further light on this observation. Elders et al. (Ref 146) reported a high rate of lumbar vertebral bone loss in late and early postmenopausal subjects, with the highest loss occurring in early postmenopause. However, no significant interaction was observed between menopausal status of the subjects and the effect of calcium supplementation. These authors reported a significant decrease in lumbar bone loss after 2 years for women treated daily with 1,000 mg and 2,000 mg of elemental calcium relative to controls. The effect of calcium supplementation was significant after the first year of supplementation but not after the second year. The authors speculate that calcium supplementation probably reduced bone turnover.

In a double-blind, placebo controlled trial in Caucasian, postmenopausal women, with low initial forearm bone density, Prince et al. (Ref. 147) showed significantly less bone loss in the distal forearm in those women treated with calcium and regular exercise, while a group treated with estrogen and regular exercise gained significant bone density at this site relative to the control group with normal initial bone density and the group treated with exercise alone. Thus, calcium supplementation and exercise slowed bone loss relative to exercise alone but less effectively than exercise combined with estrogen.

In the third prospective study, this one a 3-year study in 622 Caucasian women, Tilyard and co-workers measured rate of vertebral fractures in women treated twice a day with either 0.25 micrograms of calcitriol (a synthetic form of the active metabolite of vitamin D) or 1 gram of elemental calcium (Ref. 149). After 2 and 3 years, a significant reduction in the rate of vertebral fracture was observed in calcitriol-treated women relative to those treated with calcium alone. This study clearly demonstrates that supplementation of calcium intake alone is not adequate to prevent vertebral fracture in postmenopausal women. In the absence of placebo-treated controls, the contribution of calcium supplementation to the reduction in vertebral fracture cannot be estimated. The results of these three prospective clinical trials support the hypothesis that adequate calcium intake helps to slow the rate of bone loss in postmenopausal women, but that calcium alone cannot effectively arrest this process, especially in early postmenopause.

The third question considered in evaluating the recent literature was whether any of the studies showed a threshold effect for the level of calcium intake associated with changes in bone mass. None of the findings from the recent studies were pertinent to this question.

To summarize, these new findings were consistent with and strengthened the conclusion that adequate calcium intake has a significant impact on bone health and risk of osteoporotic fracture.

IV. Decision to Authorize a Health Claim Relating Adequate Calcium Intake to Osteoporosis

The agency has reviewed recently published research articles and review articles relevant to calcium intake and osteoporosis (Refs. 144 through 156) and has concluded that the new studies are consistent with the tentative conclusions drawn in its proposed rule on calcium and osteoporosis (56 FR 60689) . The agency also considered all comments received in response to the proposal. The overwhelming concurrence among the experts in this area and the totality of publicly available evidence supports an association between adequate calcium intake and risk of osteoporosis. Based on the totality of the publicly available scientific evidence, FDA has determined that there is significant scientific agreement among qualified experts that a health claim for calcium and osteoporosis is supported by the evidence. Under § 101.72, an authorized health claim will convey the message that an adequate intake of calcium throughout life may delay the development of osteoporosis and ultimately reduce the risk of bone fracture in some individuals later in life.

V. Environmental Impact

The agency has determined that under 21 CFR 25.24(a)(11) this action is of a type that does not individually or cumulatively have significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VI. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), and along with the food labeling proposals, the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.72 is added to subpart E to read as follows:

§ 101.72 Health claims: calcium and osteoporosis.

(a) *Relationship between calcium and osteoporosis.* An inadequate calcium intake contributes to low peak bone mass and has been identified as one of many risk factors in the development of osteoporosis. Peak bone mass is the total quantity of bone present at maturity, and experts believe that it has the greatest bearing on whether a person will be at risk of developing osteoporosis and related bone fractures later in life. Another factor that influences total bone mass and susceptibility to osteoporosis is the rate of bone loss after skeletal maturity. An adequate intake of calcium is thought to exert a positive effect during adolescence and early adulthood in optimizing the amount of bone that is

laid down. However, the upper limit of peak bone mass is genetically determined. The mechanism through which an adequate calcium intake and optimal peak bone mass reduce the risk of osteoporosis is thought to be as follows. All persons lose bone with age. Hence, those with higher bone mass at maturity take longer to reach the critically reduced mass at which bones can fracture easily. The rate of bone loss after skeletal maturity also influences the amount of bone present at old age and can influence an individual's risk of developing osteoporosis. Maintenance of an adequate intake of calcium later in life is thought to be important in reducing the rate of bone loss particularly in the elderly and in women during the first decade following menopause.

(b) *Significance of calcium.* Calcium intake is not the only recognized risk factor in the development of osteoporosis, a multifactorial bone disease. Other factors including a person's sex, race, hormonal status, family history, body stature, level of exercise, general diet, and specific life style choices such as smoking and excess alcohol consumption affect the risk of osteoporosis.

(1) Heredity and being female are two key factors identifying those individuals at risk for the development of osteoporosis. Hereditary risk factors include race: Notably, Caucasians and Asians are characterized by low peak bone mass at maturity. Caucasian women, particularly those of northern European ancestry, experience the highest incidence of osteoporosis-related bone fracture. American women of African heritage are characterized by the highest peak bone mass and lowest incidence of osteoporotic fracture, despite the fact that they have low calcium intake.

(2) Maintenance of an adequate intake of calcium throughout life is particularly important for a subpopulation of individuals at greatest risk of developing osteoporosis and for whom adequate dietary calcium intake may have the most important beneficial effects on bone health. This target subpopulation includes adolescent and young adult Caucasian and Asian American women.

(c) *Requirements.* (1) All requirements set forth in § 101.14 shall be met.

(2) Specific requirements. (i) *Nature of the claim.* A health claim associating calcium with a reduced risk of osteoporosis may be made on the label or labeling of a food describe in paragraph (c)(2)(ii) of this section, provided that:

(A) The claim makes clear that adequate calcium intake throughout life is not the only recognized risk factor in this multifactorial bone disease by listing specific factors, including sex, race, and age that place persons at risk of developing osteoporosis and stating that an adequate level of exercise and a healthful diet are also needed;

(B) The claim does not state or imply that the risk of osteoporosis is equally applicable to the general United States population. The claim shall identify the populations at particular risk for the development of osteoporosis. These populations include white (or the term "Caucasian") women and Asian women in their bone forming years (approximately 11 to 35 years of age or the phrase "during teen or early adult years" may be used). The claim may also identify menopausal (or the term "middle-aged") women, persons with a family history of the disease, and elderly (or "older") men and women as being at risk;

(C) The claim states that adequate calcium intake throughout life is linked to reduced risk of osteoporosis through the mechanism of optimizing peak bone mass during adolescence and early adulthood. The phrase "build and maintain good bone health" may be used to convey the concept of optimizing peak bone mass. When reference is made to persons with a family history of the disease, menopausal women, and elderly men and women, the claim may also state that adequate calcium intake is linked to reduced risk of osteoporosis through the mechanism of slowing the rate of bone loss;

(D) The claim does not attribute any degree of reduction in risk of osteoporosis to maintaining an adequate calcium intake throughout life; and

(E) The claim states that a total dietary intake greater than 200 percent of the recommended daily intake (2,000 milligrams (mg) of calcium) has no further known benefit to bone health. This requirement does not apply to foods that contain less than 40 percent of the recommended daily intake of 1,000 mg of calcium per day or 400 mg of calcium per reference amount customarily consumed as defined in § 101.12 (b) or per total daily recommended supplement intake.

(ii) *Nature of the food.* (A) The food shall meet or exceed the requirements for a "high" level of calcium as defined in § 101.54(c);

(B) The calcium content of the product shall be assimilable;

(C) Dietary supplements meet the United States Pharmacopeia (U.S.P.) standards for disintegration and dissolution applicable to their component calcium salts, except that dietary supplements for which no U.S.P. standards exist shall exhibit appropriate assimilability under the conditions of use stated on the product label;

(D) A food or total daily recommended supplement intake shall not contain more phosphorus than calcium on a weight per weight basis.

(d) *Optional information.* (1) The claim may include information from paragraphs (a) and (b) of this section.

(2) The claim may include information on the number of people in the United States who have osteoporosis. The sources of this information must be identified, and it must be current information from the National Center for Health Statistics, the National Institutes of Health, or "Dietary Guidelines for Americans."

(e) *Model health claim.* The following model health claims may be used in food labeling to describe the relationship between calcium and osteoporosis:

Model Health Claim Appropriate for Most Conventional Foods:

Regular exercise and a healthy diet with enough calcium helps teen and young adult white and Asian women maintain good bone health and may reduce their high risk of osteoporosis later in life.

Model Health Claim Appropriate for Foods Exceptionally High in Calcium and Most Calcium Supplements:

Regular exercise and a healthy diet with enough calcium helps teen and young adult white and Asian women maintain good bone health and may reduce their high risk of osteoporosis later in life. Adequate calcium intake is important, but daily intakes above about 2,000 mg are not likely to provide any additional benefit.

Dated: December 17, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Food and Drug Administration

21 CFR Part 101

[Docket No. 91N-0103]

RIN 0905-AB67

Food Labeling: Health Claims and Label Statements: Omega-3 Fatty Acids and Coronary Heart Disease

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision not to authorize the use on the label or labeling of foods of health claims relating to an association between omega-3 fatty acids and coronary heart disease (CHD). The agency has determined, based on: (1) The totality of the publicly available scientific evidence; and (2) the agency's review of comments received in response to its November 27, 1991, proposed rule on omega-3 fatty acids and CHD, including scientific information included in those comments, that there is not significant scientific agreement among experts that such evidence supports a health claim for omega-3 fatty acids and CHD. Further, FDA has determined that the new information does not change the conclusions that the agency reached on the basis of the information reviewed in its proposal. Therefore, FDA has concluded that such a claim is not justified. This action is in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims, and is developed in accordance with the final rule on general requirements for health claims, published elsewhere in this issue of the Federal Register.

EFFECTIVE DATE: May 8, 1993.

FOR FURTHER INFORMATION CONTACT: John C. Wallingford, Center for Food Safety and Applied Nutrition (HFS-465), Food and Drug Administration, 200 C St. SW., Washington, DC 20204, 202-205-5461.

SUPPLEMENTARY INFORMATION:

I. Background

In the Federal Register of November 27, 1991 (56 FR 60663), FDA proposed not to authorize a health claim relating diets high in omega-3 fatty acids to reduced risk of heart disease. The proposed rule was issued in response to provisions of the 1990 amendments (Pub. L. 101-535) that bear on health claims and in accordance with the proposed general requirements for health claims for food (November 27, 1991, 56 FR 60537). As amended in 1990, the Federal Food, Drug, and Cosmetic Act (the act) provides that a food is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition unless the claim is made in accordance with section 403(r)(3) or (r)(5)(D) of the act (21 U.S.C. 343(r)(3) or (r)(5)(D)).

Congress enacted the health claims provisions of the 1990 amendments to help U.S. consumers maintain good health through appropriate dietary patterns and to protect consumers from unfounded health claims. Section 3(b)(1)(A) of the 1990 amendments specifically requires the agency to determine whether health claims for 10 nutrient-disease relationships meet the requirements of section 403(r)(3) or (r)(5)(D) of the act. The relationship of omega-3 fatty acids and heart disease is one of the claims required to be evaluated. In the Federal Register of March 28, 1991 (56 FR 12932), FDA published a notice requesting scientific data and information on the 10 specific topic areas identified in the 1990 amendments. Relevant scientific studies and data received in response to this request were considered as part of the agency's review of the scientific literature on omega-3 fatty acids and CHD and were included in the proposed rule.

In addition, on January 30 and 31, 1992, FDA held public hearings on all aspects of the proposed rules (57 FR 239).

FDA requested in the Federal Register of November 27, 1991 (56 FR 60663), written comments in response to its proposed rule. FDA reviewed all of the comments it received, including new data submitted in the comments, and scientific articles referred to in the comments. FDA also reviewed additional scientific articles, reviews, and recommendations published from August 1991 through February 1992.

The Dietary Supplement Act of 1992 (DS Act) established a moratorium on the implementation of the 1990 amendments with respect to dietary supplements. The DS Act says that FDA can grant health claims for food, including dietary supplements, under section 403(r)(3)(B)(i) of the act. However, it may not act on such claims under section 403(r)(5)(D) of the act until it establishes a standard to implement that section of the act, which the DS Act says may not occur until December 1993. Section 3(b)(1)(A)(x) of the 1990 amendments directs the agency to evaluate the omega-3 fatty acids/CHD claims based on the standard that FDA is establishing for determining the reliability of health claims under section 403(r)(5)(D) of the act. In the November 27, 1991, proposal on general requirements for health claims, FDA proposed to adopt the standard that the 1990 amendments provide for conventional foods, which is set forth in section 403(r)(3)(B)(i) of the act, as the standard for dietary supplements. Given this fact, and the fact that omega-3 fatty acids are found in numerous conventional foods as well as in dietary supplements, FDA broadened its inquiry to a determination as to whether it should grant a health claim on omega-3 fatty acids and CHD for any foods.

Because the DS Act provides that FDA may grant claims using the significant scientific agreement standard specified in section 403(r)(3)(B)(i) of the act, and given the breadth of FDA's November 1991, proposal on omega-3 fatty acids, FDA has decided to move forward to determine whether it can authorize a claim under section 403(r)(3)(B)(i) for omega-3 fatty acids and CHD.

However, this rule does not apply to dietary supplements. While a manufacturer of a dietary supplement can make a claim on omega-3 fatty acids and CHD without rendering its product misbranded under section 403(r)(1)(B) of the act, the manufacturer should assure itself that the making of the claim will not misbrand the product under section 403(a).

II. Summary of Comments and the Agency's Response

FDA received 80 letters, each containing one or more comments, from consumers, health care professionals, universities and research institutes, health profession associations, consumer advocacy organizations, State and local governments, foreign governments, trade organizations, industry, and professional organizations. In addition to these comments, the agency also considered statements made on omega-3 fatty acids and CHD at the January 30 and 31, 1992, public hearings. Some of the comments agreed with one or more of the aspects of the proposed rule, without providing further grounds for support other than those provided by FDA in the preamble to the proposal. Other comments disagreed with one or more aspect of the proposal without providing specific grounds for the disagreement. A few comments addressed issues outside of the scope of this document and will not be discussed in this document. Most of the comments provided specific grounds in support of their positions concerning aspects of this health claim

as proposed. The agency has summarized and addressed the issues raised in the sections of this document that follow.

A. General Comments

1. Definition of omega-3 fatty acids and composition of omega-3 fatty acid supplements

1. One comment criticized the definition of omega-3 fatty acids used in the proposed rule, on the basis that omega-3 fatty acids were not distinguished from other polyunsaturated fatty acids (PUFA's).

In the proposed rule, FDA limited the term omega-3 fatty acids to eicosapentaenoic acid ((EPA), 20 carbons, 5 double bonds) and docosahexaenoic acid ((DHA), 22 carbons, 6 double bonds) (56 FR 60663 at 60664). FDA noted that most of the relevant research has used fish or fish oils rich in these two fatty acids.

FDA acknowledges that its statement defining omega-3 fatty acids did not explicitly refer to omega-3 fatty acids. The sentence: "Their unique characteristic is the location of the first double bond, which occurs at the third carbon from the methyl (or omega) end of the fatty acid." (56 FR 60663 at 60664) was intended to refer to omega-3 fatty acids. This definition distinguishes omega-3 fatty acids from other PUFA's, which have their first unsaturation at the sixth or ninth carbon from the omega end of the fatty acid.

2. One comment argued that the definition of omega-3 fatty acids should include land-based (primarily plant) omega-3 fatty acids (i.e., linolenic acid). (For the purposes of this document, the term linolenic acid is used to indicate the omega-3 fatty acid, alpha linolenic acid. In contrast, gamma linolenic acid has its first double bond at the sixth carbon from the omega end of the fatty acid, and is not an omega-3 fatty acid.)

FDA disagrees with this comment. FDA defined omega-3 fatty acids as EPA and DHA, primarily as a functional definition derived from the scientific literature. The hypothesis for a relationship between omega-3 fatty acids and CHD derived from correlations between low rates of CHD and high consumption of fish oils. Similarly, most of the intervention studies have used fish oil or fish as a source of EPA and DHA, not plant oils rich in linolenic acid. The comment provided no evidence that linolenic acid has biochemical effects comparable to EPA or DHA, nor has FDA found any evidence of a relationship between linolenic acid and CHD. Moreover, only a limited amount of linolenic acid is converted in the body to EPA and DHA (Ref. 100). Therefore, FDA believes it has represented the potential nutrient-disease relationship appropriately by limiting its attention to EPA and DHA.

3. Two comments stated that FDA's position on fish as opposed to the omega-3 fatty acids in fish was a tautology, because: "if polyunsaturated fatty acids have beneficial effects on CHD, and if fish oils are a member of this class of fatty acids, it should not be counted against their beneficial effects on CHD."

FDA disagrees with this comment. FDA considers the claim for omega-3 fatty acids to reflect the unique biochemistry of these fatty acids. In particular, the prevailing theory about the mode of action of omega-3 fatty acids is that they compete with omega-6 fatty acids (fatty acids with their first double bond at the sixth carbon from the methyl end, and which comprise the largest amount of dietary PUFA's). Thus, a clear separation of effects of omega-3 fatty acids from effects of other (primarily omega-6) PUFA's is needed to support a claim.

4. One comment stated that FDA did not consider the importance of the ratio of omega-3 fatty acids to arachidonic acid (AA), a 20 carbon omega-6 PUFA with four double bonds, and stated that evidence exists for a relationship between the saturated fat:unsaturated fat ratio in the diet and the omega-6:omega-3 fatty acid ratio in the diet and the risk of CHD.

FDA considers concerns about the ratio of AA to omega-3 fatty acids and the ratio of omega-6 fatty acids to omega-3 fatty acids to be reasonable in view of the competition between these classes of fatty acids in human biochemistry. FDA considered all types of foods and supplements used to provide omega-3 fatty acids in its evaluation of the claim. Although the AA content of the supplement was often reported, studies did not report data for total dietary AA. FDA is aware of only very limited data regarding the ratios of AA to omega-3 fatty acids, and of the omega-6 fatty acid:omega-3 fatty acid ratio in the diet and the risk of CHD. Therefore, it is not possible for FDA to draw any conclusions about these ratios and their possible modifying effects on the omega-3 fatty acids CHD health claim.

However, because the fish oils used contained high concentrations of omega-3 fatty acids, FDA believes that the amounts of fish oils supplemented to the various test diets would have affected the AA:omega-3 fatty acid ratio and the omega-6:omega-3 fatty acid ratio of the diets to some extent. FDA advises that interested persons may petition FDA under § 101.70 (21 CFR 101.70) to issue a regulation regarding a health claim that relates these ratios to the risk of CHD.

5. Another comment pointed out that supplements used currently have contained various amounts of short- and long-chain omega-3 fatty acids and that many supplements also contain saturated fat. The comment stated that some of the discrepancies in reported findings may be due to the type of supplement used.

FDA agrees that numerous supplements varying in fatty acid composition have been used, and that the variation in the fatty acid composition of supplements may have influenced the outcome. FDA reexamined the studies cited in its proposal and the new data submissions for evidence that the nature of the supplement used was related to the outcome. However, the agency found that the same results are observed regardless of the source of omega-3 fatty acids. For example, in eight well-designed studies cited in the proposal on the total serum cholesterol response among normal subjects (Refs. 6, 9, 14, 49, 54, 73, 156, and 166), six different sources of omega-3 fatty acids were used: Salmon oil, SuperEPA, MaxEPA, a fish oil triglyceride, Promega, and mackerel paste. None of these supplements produced a change in total serum cholesterol. Similarly, four different sources of omega-3 fatty acids (fresh water fish, salmon oil, purified EPA, MaxEPA) were shown in seven well-designed studies to reduce platelet aggregation in normal subjects (Refs. 2, 6, 24, 54, 96, 143, and 166).

FDA did note that some differences in response have been produced by supplements that vary in ratio of EPA to DHA. For example, one fish oil (pollock oil) with a high EPA:DHA ratio increased low-density lipoprotein (LDL) cholesterol, LDL triglyceride and apoprotein B (apoB) (a protein component of LDL) in comparison to a butter-rich diet, but two fish oils with a low EPA:DHA ratio (tuna oil, salmon oil with added palmitic acid) reduced apoB and LDL cholesterol, and increased LDL triglyceride to a smaller extent than the pollock oil in comparison to the butter-rich diet (Ref. 17). However, the effects of the two major omega-3 fatty acids have not yet been systematically investigated. FDA recognizes that purified EPA and DHA are now available for research; such supplements will enable the study of the individual effects of these fatty acids.

6. One comment stated that conservation of omega-3 fatty acids in

the body calls into question the importance of the amounts of omega-3 fatty acids used in scientific studies. However, the comment did not suggest any alternate method to describe intake.

FDA recognizes that fish is not ordinarily consumed daily. However, the 1990 amendments require that health claims on foods be stated in such a way as to enable the public to understand the relative significance of such information in the context of a total daily diet (section 403(r)(3)(B)(iii) of the act). Thus, a reasonable estimate of daily dietary intake of omega-3 fatty acids is needed when assessing the relationship between omega-3 fatty acids and the risk of CHD. Most of the studies reviewed by the agency used daily supplementation with a known amount of omega-3 fatty acids, but others estimated intake of omega-3 fatty acids from foods consumed in the daily diet. Both types of intake estimates are important. Daily supplementation is useful to relate changes to a carefully controlled amount of omega-3 fatty acids. The average daily intake of omega-3 fatty acids in nonintervention studies provides a basis upon which to determine whether the amounts of omega-3 fatty acids fed in supplementation studies are reasonable in the context of the total daily diet.

2. Criteria used in evaluating studies

In the proposed rule, FDA listed some of the criteria used in evaluating epidemiological studies on the relationship of omega-3 fatty acids to CHD: (1) The reliability and accuracy of the methods used in food intake analysis and measurements of disease endpoints, (2) the choice of control subjects, (3) the representativeness of the subjects, (4) the control of confounding factors in data analysis, (5) the potential for misclassification of individuals with regard to dietary exposure or disease endpoints, (6) the presence of bias, and (7) the degree of compliance and how compliance was assessed (56 FR 60667).

However, FDA stated that it considered randomized, double-blind, placebo-controlled trials to be more valuable than other types of human studies because they were less susceptible to bias, and because they allowed inference about the specific effects of omega-3 fatty acids. Studies in which the endpoint was CHD, by definition, provide the most persuasive type of evidence, but studies measuring CHD to date have not provided the specificity to show that the observed effects were due to omega-3 fatty acids.

7. Some comments expressed the concern that it was unlikely that additional clinical trials will be done due to their expense, and that, therefore, FDA should rely more heavily on epidemiologic studies, animal studies, and biochemical and physiological interventions that suggest an effect of omega-3 fatty acids on risk of CHD.

FDA has no basis upon which to agree or disagree with the comments' assertion that further clinical trials are unlikely. FDA disagrees that its emphasis on clinical trials was misplaced. Because the 1990 amendments addressed nutrient-disease relationships, FDA considered human studies that used CHD as the endpoint to be the most directly relevant studies, although these studies do not demonstrate that the effects are specifically due to omega-3 fatty acids. Human studies in which a surrogate marker for CHD risk was measured as the endpoint of the treatment were also considered carefully. The advantage of these studies is that they are able to demonstrate specificity of the effects due to omega-3 fatty acids. However, the relationships between many of these surrogate markers and risk of CHD are not well established, making it difficult to relate changes in these endpoints brought about by omega-3 fatty acids to the risk of disease. Biologic markers can serve as markers of a developing disease, but the relevance of such evidence depends directly on the strength of the association between the marker and the disease (Ref. 115).

FDA agrees that there are considerable additional data in animal studies, in vitro studies, and biochemical and physiological interventions regarding the effects of omega-3 fatty acids. However, it is not clear that the results of such studies are relevant to the risk of human disease. Thus, FDA believes that these other types of data are of secondary importance compared to clinical data that measure either CHD per se or established surrogate markers for CHD.

However, in response to the comments, FDA has provided a more thorough description of animal and in vitro studies that suggest a role for omega-3 fatty acids in reducing the risk of CHD, particularly with respect to the effects of omega-3 fatty acids on the development of atherosclerosis and with respect to the responsiveness of blood vessels to ischemia (see comments 38 and 49 and section II.C.3.a. of this document).

8. Many comments stated that the agency's position on omega-3 fatty acids and CHD was inconsistent with its position on other health claims, and argued that for each of the four claims proposed to be allowed by FDA, the data were no stronger than the data supporting the link between omega-3 fatty acids and CHD. The comments asserted that, by basing its decision on the relationship between the nutrient and a surrogate marker for the disease, or for a susceptible subpopulation, FDA held other claims to a less restrictive standard. One comment stated: "The FDA statement is internally consistent in denying health claims for omega-3 fatty acids, but this is only in the context of holding these food components to essentially impossible standards not required for other, allowable, claims."

Specific comparisons were made to the proposed claims on fat and CHD, fat and cancer, calcium and osteoporosis, and sodium and hypertension. Other comments indicated that qualified claims, such as that for calcium and osteoporosis, were appropriate models for the claim relating omega-3 fatty acids to CHD.

FDA disagrees with these comments. FDA believes that for these other claims there is significant scientific agreement among qualified experts regarding the relationship between the nutrient and the disease, whereas there is not such agreement regarding the relationship between omega-3 fatty acids and CHD, or between omega-3 fatty acids and agreed surrogate markers for risk of CHD. For example, based on the totality of the publicly available scientific evidence, FDA determined that there is significant scientific agreement about the role of calcium in maintaining bone mineral density (the relationship of the nutrient to the intermediate marker for the disease), and about the relationship between peak (maximal) bone mass and the risk of developing osteoporosis and related bone fractures later in life (the relationship between the intermediate marker and the disease itself) (see 56 FR 60689; see also the final rule on calcium and osteoporosis published elsewhere in this issue of the Federal Register). Similarly, FDA relied on a long history of Federal Government and other consensus statements to conclude that there is significant scientific agreement about the role of sodium as a causal factor in hypertension for a segment of the population. (See 56 FR 60825; see also the final rule on sodium and hypertension, published elsewhere in this issue of the Federal Register.) FDA also recognized the history of significant scientific agreement about the relationships between fat and cancer and between fat and CHD evidenced by statements in reports issued by Federal Government and other authoritative bodies. (See 56 FR 60764, 56 FR 60726; see also final rules on fat and cancer and

fat and CHD, published elsewhere in this issue of the **Federal Register**.).

Thus, these other nutrient-disease relationships have a history of being recognized in Federal Government and authoritative reports, indicating significant scientific agreement, whereas the relationship between omega-3 fatty acids and CHD has not been so recognized. For two of these other nutrient-disease relationships, the data relate to the disease itself, rather than to markers for the disease. In the other two, calcium and osteoporosis and fat and CHD, there is significant scientific agreement that the dietary factors are related to surrogate markers for the diseases, and that the surrogate markers are related to the diseases.

There is significant scientific agreement that serum cholesterol and blood pressure are risk factors for CHD, as indicated by the emphasis on these factors in Federal Government and other authoritative documents (Refs. 34 through 36, 100, 115, and 169). Data regarding the effects of omega-3 fatty acids on these endpoints have been carefully reviewed. However, the other endpoints measured in studies of the effects of omega-3 fatty acids, e.g., in vitro platelet aggregation, various growth factors, fibrinogen, have not achieved the same extent of scientific agreement.

Where authorized health claims include qualifications, the qualifications are intended to assure that the wording of allowed claims reflects those particular aspects of the substance-disease relationship for which there is significant scientific agreement, not to qualify the extent of agreement.

9. Some comments stated that FDA relied heavily on material published in the National Academy of Sciences 1989 report, "Diet and Health: Implications for Reducing Chronic Disease Risk" (Ref. 115) and the Surgeon General's 1988 report (Ref. 34), and did not place enough emphasis on information published since that time.

FDA acknowledges that the two reports in question were important to its assessment of the scientific evidence. However, the agency does not agree that it failed to give appropriate weight to subsequently published research. The 1990 amendments required the agency to consider the totality of publicly available scientific evidence in assessing nutrient-disease relationships. Given the time constraints imposed by the 1990 amendments for developing and publishing proposed regulations, FDA depended on Federal Government reports and reports of authoritative bodies (e.g, the National Academy of Sciences) for assessment of the scientific evidence published before 1988. The reports were also used as a way of determining whether there was significant scientific agreement among qualified experts that the evidence supports a relationship between omega-3 fatty acids and CHD. The agency's reliance on these reports is consistent with the 1990 amendments, which require the agency to consider reports from authoritative scientific bodies of the United States in assessing health claim petitions and to justify any decision rejecting the conclusions of such reports (section 403(r)(4)(C) of the act).

Recognizing, however, that considerable research had been published since these reports, and that these reports had not been updated, FDA also reviewed the available studies on humans published since 1988. FDA relied on its own review of individual studies rather than review articles, because review articles generally reflect the bias of the author and may not consider the totality of the evidence. FDA focused its independent review on primary papers published between January 1988 and August 1991. Surveys and cross-sectional or prospective studies that were published before 1988 and used to generate the hypothesis of a relationship between omega-3 fatty acids and CHD were also reexamined. Thus, by utilizing the two reports in question, supplemented with an independent review of the subsequently published research, FDA was able to assess the totality of the scientific evidence on omega-3 fatty acids and CHD in compliance with the statutory standard.

10. One comment suggested that FDA was inconsistent with the conclusions of the major reviews of this area, published after the Federal Government and other comprehensive reports. They stated that of the nine major reviews (excluding Kinsella, and Connor and Connor), eight concluded that omega-3 fatty acids played a beneficial role with factors affecting heart disease.

Although FDA did not rely on review articles to assess the strength of association between omega-3 fatty acids and CHD, each review was read, and the agency interprets these reviews as supporting the hypothesis in concept. However, each review contained reservations about the extent to which the relationship between omega-3 fatty acids and CHD was established. The cautionary statements suggest general agreement that the area of omega-3 fatty acids and CHD holds promise for further research along a number of lines, but that, at present, there are not sufficient data to have certainty about the relationship between omega-3 fatty acids and CHD. Placed in chronological order, the concluding sections from the cited review articles exemplify the lack of certainty as to the relationship between omega-3 fatty acids and risk of CHD.

The review of the relationship between omega-3 fatty acids and CHD by Leaf and Weber (Ref. 91) was considered in the National Academy of Sciences' "Diet and Health: Implications for Reducing Chronic Disease Risk" report (Ref. 115). FDA elected to include the Leaf and Weber review in its citations because it covered, in the most comprehensive manner of all available reviews, the state of scientific knowledge about omega-3 fatty acids in CHD at the time the Federal Government and other comprehensive reviews were published. Leaf and Weber wrote: "Despite claims that n-3 fatty acids can help prevent atherosclerosis, recommendations to the public on diet have been conservative; people have been advised to increase their consumption of fish by replacing two or three meals a week containing red meat with meals containing fish." Their concluding sentence was: "If prospective double-blind, placebo-controlled clinical trials *were to show* that n-3 fatty acids helped to prevent atherosclerosis, these agents apparently would represent one of the most benign interventions in our pharmacopeia." (Emphasis added.)

Bonaa (Ref. 10) wrote in his conclusion that the data on blood pressure:

> * * * provide some support for the hypothesis that dietary marine lipids influence blood pressure in man. Supplementation of n-3 PUFAs [polyunsaturated fatty acids] to Western diets consistently lowered systolic blood pressure, while results for diastolic blood pressure were conflicting * * *. There is no evidence of any substantial hypotensive response to marine lipids and further studies should be designed to detect small effects.

Lands (Ref. 89) did not review the relationship between omega-3 fatty acids and any specific disease, but presented the hypothesis that the balance of omega-3 and omega-6 fatty acids in the diet may be related to diseases associated with overproduction of eicosanoids from AA. He indicates in the introduction that, "We are now in an uncertain time of evaluating the benefits and risks of dietary n-6 and n-6 polyunsaturated fats."

Weber (Ref. 161) concluded:

> The promise of n-3 fatty acids deduced from biochemical and functional effects will have to be evaluated in ongoing and future carefully designed and conducted studies. So

far, published data of controlled clinical trials incorporating clinical endpoints after n-3 PUFAs are available only in abstract form. Therefore, the gap between biochemical and functional effects of dietary fatty acids *assumed to be* of clinical benefit in the prevention of atherothrombotic and allergic/inflammatory disorders is only beginning to be closed. (Emphasis added.)

Connor and Connor (Ref. 21) wrote in their summary:

The exact place of omega-3 fatty acids from fish and fish oil remains to be defined. However, this much seems certain. Fish provides an excellent substitute for meat in the diet. Fish is lower in fat, especially saturated fat, and contains the omega-3 fatty acids. Fish oil may have promise as a therapeutic agent in certain hyperlipidemic states, especially the chylomicronemia of type V hyperlipidemia. Fish oil has logical and well-defined antithrombotic and antiatherosclerotic activities since it depresses thromboxane A2 production and inhibits cellular proliferation responsible for the progression of atherosclerosis. As the years pass and more experiments are reported, it seems reasonable to place the omega-3 fatty acids from fish oil in a prominent position for specific hypolipidemic, antithrombotic and antiatherosclerotic activity.

Kinsella et al. (Ref. 82) wrote:

The cumulative findings concerning fish oils suggest that further amelioration of coronary heart disease may be feasible by dietary manipulation and by optimizing the intake of n-6 and n-3 PUFAs, not only to reduce plasma lipids but to ensure balanced eicosanoid metabolism—a prospect that deserves more research * * *. Overall, in view of the prevalence of coronary heart disease, consumption of n-3 PUFA oils should be considered as a useful complementary option for the amelioration of coronary vascular diseases.

Knapp (Ref. 84) introduced his paper stating: "The role of dietary polyunsaturated fats in the prevention of human vascular disease *has not been defined*, but population and intervention studies have *suggested* that w-3 fatty acids (FAs) from marine lipids *may have* a number of potentially beneficial effects." (Emphasis added.) And in conclusion he wrote: "The *proof of our hypotheses* must be derived from increasingly ambitious clinical trials, which assess the *potential* benefits of dietary polyunsaturates in particular clinical settings, the recent demonstration that three helpings of oily fish per week prolongs survival after MI (Ref. 16) is an example of this." (Emphasis added.)

Nestel (Ref. 111) concluded: "More basic understanding of the actions of fish oils is necessary before fish oils can be recommended widely to the public."

Nordoy and Goodnight (Ref. 112) cautioned that until additional data become available, "clinicians should be advised to follow the dietary recommendations of the National Cholesterol Education Program's expert panel," which is silent on omega-3 fatty acids and limits the total polyunsaturated fat to 10 percent of calories. These reviewers added their own recommendation that omega-6/omega-3 ratio of the PUFA's be approximately 3/1, with the omega-3 fatty acids from marine sources.

Weber and Leaf (Ref. 162) stated:

Despite all the laboratory, human, animal, and epidemiologic studies suggesting an anti-atheromatous action of w3 fatty acids, we have been lacking adequate clinical trials which will determine in prospective, placebo-controlled, randomized studies, whether all the above experimental and epidemiologic evidence adds up to a demonstrable effect of fish oils to prevent atherosclerosis, e.g., coronary heart disease in humans at high risk for heart attacks.

The Burr paper (Ref. 16) was described in Weber and Leaf's review, and thus was considered in the above summary statement.

In summary, these reviews indicate that what is agreed is that there is a plausible biochemical basis for a relationship between omega-3 fatty acids and CHD, and that there are some data supporting some of the hypothesized mechanisms by which omega-3 fatty acids might be related to CHD. What is not agreed, as indicated by the cautious tones of these concluding statements, is that such a relationship already has been established by the evidence.

11. A concern raised by many comments was that FDA's conclusions were different from the conclusions reached in the report from the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology (Ref. 100), the most recent comprehensive review, and that FDA did not explain why it reached a different conclusion from that reached in the LSRO report.

The LSRO report was contracted for by FDA as an independent review of the scientific evidence about the relationship between omega-3 fatty acids and CHD. A draft of the tentative final report was received immediately prior to the publication of the proposed rule. Thus, there was insufficient time for the agency to prepare a detailed discussion of the report. The final report was submitted to FDA as a comment to the proposal. The LSRO report's conclusions on hypertension, thrombosis, the development of atherosclerotic plaque and intimal hyperplasia, plasma lipids and lipoproteins, diabetic and prediabetic patients, and epidemiologic observations are grouped with other comments on these topics and discussed in this document.

12. One comment considered FDA's caution against extrapolation of results from studies conducted in at-risk populations to the general population to be questionable, and possibly biased against hypertensives. The comment stated that the health claim should be allowed, based on data showing that omega-3 fatty acids reduce blood pressure among hypertensives.

FDA disagrees with this comment. FDA stated that, although it considered studies in the healthy population to be the most relevant, it also considered studies in a subpopulation with CHD or risk factors for CHD, in part because high risk populations may be more sensitive to showing a nutrient-disease relationship than the general population (56 FR 60663 at 60667). FDA stated that it extrapolated positive results from at-risk populations cautiously, and that comparable findings in the general population were needed to support a health claim.

13. Two comments discussed FDA's criteria for weighing various types of data. One comment stated that epidemiologic data are the "most significant class of evidence," and that FDA should give priority to various types of data in the same order that various types of data were reviewed in the proposal. One comment stated that FDA should not have considered epidemiological studies separately from clinical trials.

FDA considered the totality of publicly available scientific evidence in its assessment of the relationship of omega-3 fatty acids to CHD. However, some types of evidence were weighted more heavily than others because they were more useful in establishing whether or not the scientific basis of the claim was valid. In particular, the agency was concerned that both the substance (omega-3 fatty acids) and the disease (CHD) be carefully characterized. FDA also considered it important that the amount of omega-3 fatty acids tested was reasonably related to normal dietary intake, and that the findings apply to the general population. FDA agrees that epidemiologic studies in which the endpoint was CHD provide persuasive evidence for a relationship between fish consumption and CHD, but these studies did not provide the specificity to show that the observed effects were due to omega-3 fatty acids. Intervention trials using fish oil supplements often showed that the effects were specific to omega-3 fatty acids (by controlling with

other types of fatty acids) but typically did not measure the primary endpoint, CHD. Thus, these different types of data complement each other and must be considered together in assessing the totality of the scientific evidence.

14. One comment offered the services of the International Society for the Study of Fatty Acids and Lipids for the evaluation of the relationship between omega-3 fatty acids and CHD.

FDA appreciates this offer. In the final rule on general requirements for health claims published elsewhere in this issue of the **Federal Register**, FDA advises that it welcomes the input of any professional organization that can provide expertise in reviewing data and in developing a thoughtful and well-organized petition for a health claim on a particular topic. In fact, FDA has added to § 101.70(b) the provision that information submitted with petitions may include any findings, along with the basis of the findings, of an outside panel with expertise in the subject area at issue. FDA, however, retains the authority to review such petitions and, through rulemaking, to decide whether or not to authorize the claim.

15. Two comments stated that it was contradictory for the U.S. Government to contract for research on the omega-3 fatty acids through the biologic test materials program but not to allow a health claim. Another comment pointed out that the Food and Agriculture Organization and the World Health Organization support research on omega-3 fatty acids. Other comments stated that the tone of FDA's proposed rule was unduly negative and that, by taking such a position, FDA may retard further research.

FDA disagrees that Federal Government sponsorship of a program to provide test materials for research on the effects of omega-3 fatty acids and the denial of the omega-3 fatty acid-CHD health claim are contradictory actions. The purpose of the biologic test materials program is to develop and standardize a source of omega-3 fatty acids and enable carefully controlled research on the effects of particular omega-3 fatty acids. In the proposed rule, FDA's intent was to examine the total available scientific evidence, some of which was generated using omega-3 fatty acids from the biologic materials test program, and to state its conclusions about the relationship between omega-3 fatty acids and CHD.

In its proposal and in this final rule, FDA has identified a number of areas where agreement is lacking that an observed effect of omega-3 fatty acids is related to the risk of CHD, or where there are ambiguities in the data that may be resolved by further research. Thus, FDA's analysis should provide guidance for additional research rather than inhibit it.

B. Relationship Between Omega-3 Fatty Acids and CHD

In the proposed rule, FDA tentatively concluded that the totality of the scientific evidence does not provide a basis upon which to authorize a claim that omega-3 fatty acids are associated with the risk of CHD (56 FR 60663). FDA noted that,

> the epidemiological research on this topic revealed that the available studies applied only to the consumption of fish, which contain omega-3 fatty acids, and * * * it was not possible to ascribe any effects specifically to the omega-3 fatty acids. Examination of data from clinical studies revealed that the effects on blood lipids of fish oils containing omega-3 fatty acids were primarily a reduction of blood triglycerides, a blood lipid variable not considered to be an independent risk factor for CHD, but they had no effect on serum cholesterol, low-density lipoprotein (LDL) cholesterol, or high density lipoprotein (HDL) cholesterol, the blood lipid variables most closely associated with risk of CHD The scientific data are ambiguous on the effects of omega-3 fatty acids on blood pressure and other risk factors for CHD.

(56 FR 60663.)

A number of comments supported the agency's position on this health claim, but without any specific reasons for that support. One comment agreed with the agency's position in principle, but contested the agency's interpretation of the scientific information in some areas. Other comments disagreed with the agency's review of the scientific information and its conclusion regarding the strength of the evidence supporting the proposed health claim. Specific comments are summarized below.

1. Epidemiologic evidence

In the proposed rule, FDA reviewed correlational and cross-sectional studies, prospective studies, and intervention studies available since 1988. (See 56 FR 60663 at 60667 through 60668). Except for the intervention studies (which were typically clinical trials) these studies used fish as a source of omega-3 fatty acids. FDA concluded that those studies that used fish as the source of omega-3 fatty acids were: "ambiguous, because they are not capable of distinguishing the effects that are specific to omega-3 fatty acids from those that are related to fish consumption." (56 FR 60663 at 60668.)

16. A number of comments considered the evidence from epidemiologic studies that relates the consumption of fish inversely to CHD to be sufficient to support a health claim, but did not supply any new information or arguments to support their position.

FDA disagrees with the comments. FDA found that:

> Only a few studies found an association between fish intake and CHD, while others have found no association. Thus there was not consistency of findings. None of the studies that reported a relationship distinguished fish consumption from other factors associated with fish consumption, and therefore they did not demonstrate specificity. Even in those studies reporting a relationship between fish consumption and CHD, it was not clear that the effects were because of the omega-3 fatty acids in fish. Also, the omega-3 fatty acid content of the fish diet associated with reduced CHD was so low that the importance of omega-3 fatty acids is questionable * * *

(56 FR 60663 at 60672.)

17. One comment described the results of the Dolecek and Grandits analysis of multiple risk factor intervention trial (MRFIT) data (Ref. 38) as indicating a greater protective effect against CHD due to consumption of 0 6 gram (g) omega-3 fatty acids than all other conventional efforts combined (reducing saturated fat, cholesterol, cigarette smoking, and hypertension).

FDA agrees with this comment that the association between omega-3 fatty acid consumption and CHD mortality reported in this study has the potential to make a very important public health impact. Notably, the results were obtained on data adjusted for age, race, smoking at entry to the study, diastolic blood pressure, and high-density lipoprotein (HDL) and LDL concentrations. Furthermore, the omega-3 fatty acids were obtained in the normal diet, providing evidence that the amount of omega-3 fatty acids consumed in a normal dietary intake is sufficient for the effect.

The researchers' adjustments for lipoprotein measurements should control for some other dietary variables that have been associated with CHD through their effects on these lipoproteins, e.g., saturated fat, but other dietary variables associated with CHD were not controlled, e.g., alcohol. The association between omega-3 fatty acid consumption and CHD mortality described in this study is among the most provocative findings to date in this area, and merits additional study using a design that will document that the active dietary component is or is not the omega-3 fatty acids (i.e.; specificity of the effect).

18. One comment pointed out that the Burr paper (Ref. 16) deserved close consideration, because, in contrast to

trials on lipid lowering drugs, it showed that consumption of fish containing omega-3 fatty acids or dietary supplements of omega-3 fatty acids may reduce the risk of heart disease. One comment stated that it considered the Burr paper to be a positive finding, but gave no reason for this conclusion. The LSRO final report, submitted as a comment, also recognized the Burr paper as a very important trial. LSRO pointed out that, although separate results were not shown for those consuming fatty fish and those consuming supplemental fish oil, the results were dramatic, especially since all-cause mortality was reduced, in contrast to results from trials of plasma lipid-lowering drugs. LSRO concluded that "future research will be needed to define the amount and duration of w-3 fatty acid supplementation required to produce the beneficial effects."

FDA agrees that the Burr paper provides valuable evidence consistent with the hypothesized relationship between omega-3 fatty acids and CHD. However, FDA noted in its proposal (56 FR 60663 at 60668) that there are two specific shortcomings in this paper: the absence of separate data for subjects who consumed fish and those who consumed fish oil capsules, and the absence of dose-response data. These data would have provided evidence for a specific effect of omega-3 fatty acids. Ideally, other data regarding the subjects' diet would also show that there was no difference in consumption of other dietary factors related to CHD. The study design specifically included two such dietary factors, dietary fat and dietary fiber, and the lack of significant effects of these components argues against dietary factors other than omega-3 fatty acids as responsible for the association.

FDA does not consider the Burr paper to have established a beneficial effect of omega-3 fatty acids, although its results are consistent with such an action. The LSRO conclusion indicates that neither the amount of omega-3 fatty acids necessary for beneficial effects nor the duration of their intake has been established. The specificity of the substance responsible for the beneficial effects, the quantitative amount needed to produce the effect and the duration of intake needed to produce the effect need to be established before FDA can authorize a claim linking omega-3 fatty acids to reduction of risk of CHD.

19. Some comments stated that the amount of fish in the Zutphen and Burr studies was so low that the association between fish consumption and reduced CHD mortality could not be explained by the displacement by fish of other atherogenic foods from the diet.

FDA is not persuaded by these comments. The limitation in these studies is that they did not control for dietary factors associated with CHD, not that fish consumption displaced other atherogenic foods. FDA noted in its proposal that the Zutphen study found significant correlations between fish consumption and other dietary factors (i.e., alcohol, polyunsaturated fats) related to CHD. Comparable correlations were not addressed in the Burr paper because dietary intake data were not reported. Also, the design of the Burr paper was to encourage consumption of fish, which would likely have resulted in a reduction in the consumption of red meat (and, therefore, saturated fat).

20. Two comments discounted the Curb et al. study (Ref. 25), which showed no association between fish consumption and CHD mortality among subjects in Hawaii. The comments stated that the dietary source of fish was likely tropical fish, and since tropical fish feed on coral they have a high content of AA, which would counteract the effect of omega-3 fatty acids.

FDA disagrees with the comments. No data regarding the AA content of the diet in this study, or in other correlational studies, have been reported. Indeed, most epidemiologic correlation studies have not quantified the intakes of omega-3 fatty acids, a fundamental measurement to establish an association between omega-3 fatty acids and CHD. Finally, there is an abstract reporting that the omega-3 fatty acid to omega-6 fatty acid ratio of tropical fish is comparable to or greater than that of fish in higher latitudes (Ref. 237). Thus, the comments' explanation for a negative finding must be considered theoretical.

21. One comment argued that the lack of an association between fish consumption and CHD in two populations in Canada, a prairie province and a coastal province (Ref. 74), was because the prairie population consumed more alcohol and the coastal population smoked more. This comment criticized FDA for not pointing out the cautions raised by the authors about potential confounders like the difference in alcohol consumption.

FDA believes it presented the results of this paper fairly. While the authors reported small differences in smoking (more in the coastal population) and alcohol consumption (more in the prairie population), they stated, "It seems unlikely that these differences are sufficiently large to offset any strong effect of fish consumption." FDA is keenly aware that dietary and behavioral factors (e.g., smoking, alcohol) must be controlled before meaningful conclusions may be drawn about the effects of omega-3 fatty acids. FDA notes that alcohol consumption was also a confounding factor in a study that reported an association between fish consumption and CHD (Ref. 87).

22. A few comments stated that many of the reported effects come from studies on fish consumption, but that all measured biochemical changes related to CHD that are produced by fish have also been produced with fish oil concentrates.

FDA agrees in part with this comment. The fact that the same biochemical results have been obtained using fish oils rather than fish provides strong evidence that particular biochemical markers are affected specifically by omega-3 fatty acids. Also, since most studies have used fish oils, these results add consistency to the effects reported for studies that used fish. However, FDA disagrees that the comparable findings in studies that used fish oils and fish are sufficient to support the health claim that omega-3 fatty acids reduce the risk of CHD, because the particular biochemical markers affected by both fish and fish oils are not recognized with significant scientific agreement as useful surrogate risk factors for CHD in the general population.

23. One comment argued that the fact that Greenland Eskimos ate diets with half the saturated fat and more polyunsaturated fat than Danes and had much less CHD than Danes strengthens the case for fish oil-derived omega-3 fatty acids.

FDA agrees with the comment that diets lower in saturated fat are consistent with reduced CHD mortality (see the final rule on "Dietary Lipids and Coronary Vascular Disease" published elsewhere in this issue of the Federal Register). The differences in saturated fat intake, however, do not strengthen the case for omega-3 fatty acids, because they do not distinguish omega-3 fatty acids from polyunsaturated fats. Rather, the differences in dietary fat intakes strengthens the argument that saturated fat is associated with CHD mortality. The numerous dietary differences between the Greenland Eskimos and Danes make it difficult to ascribe to any single dietary factor the differences in CHD.

24. One comment pointed out that, of the ten prospective studies cited in the proposal (including three in Table 1 of the proposal), six support an inverse relationship between fish consumption and CHD. The comment noted that one

study only showed a relationship in men under 45, and argued that this result is promising because one might expect to find positive effects of long-term fish consumption on CHD in younger, relatively healthy men rather than in older men.

FDA agrees that some but not all reports find an inverse relationship between fish consumption and CHD. FDA does not agree, however, that this effect would more likely be noticed among younger, relatively healthy men. Older men would have had a greater duration of intake of omega-3 fatty acids and a greater incidence of CHD than younger men. Both these factors would favor finding an effect in older men rather than in younger men.

25 One comment noted that only two studies found a positive dose-response. Another comment stated that the studies that show no effect are those where the base group already consumed fish, whereas in studies that showed an effect, the base group did not consume fish A third comment stated that there were data that described an inverse dose-response relationship between serum EPA and CHD deaths among Japanese, but did not identify a particular study.

FDA disagrees that only two studies found a dose response correlation. Each study that reported a relationship between fish consumption (or, in one study, the calculated intake of omega-3 fatty acids) and CHD found a dose-response relationship. FDA agrees that most of the dose-response relationships reported suggest that the primary difference in rate of CHD is between those who consume no fish at all and those who consume a small amount of fish, and that there appears to be little additional benefit from consumption of large amounts of fish (Ref. 88). An alternate way of describing these data is that those who consume no fish have an increased risk of CHD. These data merit followup, because a showing that the relationship is due to the omega-3 fatty acids may provide evidence that the long-chain omega-3 fatty acids are essential in the diet.

In its proposal, FDA reviewed a study that described an inverse dose-response relationship between serum EPA and CHD mortality among two groups of Japanese (Ref. 78). FDA concluded that these cross-sectional, correlational data were useful in generating a hypothesis. Other notable dietary factors (including a difference in salt intake of 50 percent) and risk factors for CHD (prevalence of hypertension) also differed between the two groups, so it is not possible to conclude that differences in CHD mortality were due to differences in dietary omega-3 fatty acids.

26. Two comments stated that FDA had erred in stating that no biochemical data were reported in the Burr paper (Ref. 16).

FDA agrees with this comment, and stands corrected. Burr et al. (Ref. 16) did report that the geometric mean percentages of EPA were 0.59 percent and 0 46 percent in men given advice to consume more fish and those not so advised, respectively, a highly significant difference ($p < 0.01$). The fact that a geometric mean rather than an arithmetic mean was reported implies that there was substantial skewing of the data.

It is not clear from the article whether these differences were for the 6-month time into the trial, or for the end of the trial. The authors did not correlate plasma EPA concentrations directly with myocardial infarction (MI) or CHD deaths.

27. One comment argued that it was highly misleading to state in Table 1 that Kromhout et al. (Ref. 87) reported that, "lean fish, low in omega-3 fatty acids, had some protective effect against CHD," because Kromhout did not distinguish between the effects of lean and fatty fish.

FDA disagrees with this comment. The authors made two statements about lean fish that imply that additional data analyses were conducted, although (as the comment correctly notes) results of these analyses were not included in the paper. The authors wrote, "Lean fish was also inversely related to mortality from coronary heart disease," and "Thus, the inverse relation between lean fish and coronary heart disease cannot be explained by eicosapentaenoic acid."

FDA interprets these comments as a caution to the reader against assuming that EPA was the active component responsible for the observed reduction in CHD among fish-consuming subjects.

28. LSRO included in its report two studies that correlated plasma omega-3 fatty acids with dietary intake of these fatty acids (Refs. 213 and 225). Two other papers reviewed by LSRO but not included in the FDA proposal were correlation studies of mortality from different diseases among Greenlanders and Danes (Ref. 176) and diet-disease correlations in Japan (Ref. 284).

FDA agrees with LSRO's descriptions of these studies. FDA notes that the authors of the studies that correlated intake and plasma levels of omega-3 fatty acids did not relate their data to CHD The correlation studies of mortality did not provide any specific data regarding omega-3 fatty acids.

29. One comment provided new dose-response data from additional analyses of data of the Dart study, previously reported in part by Burr et al. (Ref. 16), that related the dietary intake of EPA at 6 months into the trial to the risk of CHD events (heart attacks, or MI's) or CHD mortality. The 947 subjects for whom dietary data were obtained were grouped according to EPA intake; 114 consumed less than 1 g per week (1 g/week), 373 consumed 1 to 2 g/week, and 460 consumed 2 or more g/week. The percentage of subjects that experienced either a nonlethal heart attack or died from a heart attack decreased as dietary EPA increased. For heart attacks the rates were 7.9 percent, 7.0 percent and 6.7 percent, for the less than 1 g/week, 1 to 2 g/week and 2 or more g/week groups, respectively. The percentages in each group who died were 6.1 percent, 5.1 percent, and 4.1 percent, respectively. There were no statistical analyses of these data reported.

FDA notes some limitations in these data as reported that caution against strong conclusions. Most notably, the analysis excluded the events and deaths during the first 6 months of the trial, when about half of all events and deaths occurred. This clearly diminishes the sensitivity of the analysis, and may result in an underestimation of the true effect, since the difference in survival between the group advised to eat more fish and the group not advised to eat more fish was most pronounced during the first 6 months. Alternatively, if the healthiest subjects were also the most compliant subjects, the reduced death rate in the highest EPA-consumption subjects may reflect the underlying health of those subjects, and the importance of dietary EPA may be overestimated.

Also, the unequal group sizes for this analysis places a greater weight on each subject in the smallest group (less than 1 g/week) than in the other groups. This may be particularly important because the smallest group includes those who consume no fish, and who may differ from fish consumers in other dietary or behavioral factors associated with CHD risk. The sensitivity of the results to small changes in outcomes is shown by example: one fewer death (6/114 rather than the reported number, 7/114) makes the CHD death rate of the less than 1 g/week group equal to the rate in the 1 to 2 g/week group.

Finally, although the dietary intake data at 6 months are useful, this study also assayed plasma fatty acids. Use of plasma EPA (or EPA plus DHA) in the dose-response analysis would have been a more powerful analysis, because it eliminates errors in the diet record data,

corrects for losses during food preparation and individual differences in bioavailability of the fatty acids, and integrates intake of omega-3 fatty acids over a longer period than the diet record data.

Therefore, FDA finds these dose-response data to be consistent with the hypothesis that omega-3 fatty acids reduce the risk of CHD, but the shortcomings discussed above limit their usefulness in establishing a relationship between omega-3 fatty acids and risk of CHD.

2. Evidence relating omega-3 fatty acids to intermediate or surrogate markers of CHD

In the proposed rule (56 FR 60663 at 60668), FDA stated that most information about the effects of omega-3 fatty acids on CHD has been derived from clinical trials using concentrated fish oils enriched in EPA and DHA, and in some cases purified methyl or ethyl esters of EPA and DHA. FDA concluded that:

> * * * there are a few established effects of omega-3 fatty acids from fish oils on thrombosis and hemostasis. Standardized bleeding times are increased, and platelet aggregation and function are reduced. However, direct relationships between the changes in bleeding times or platelet function and risk of CHD have not been established. While there is an established relationship between blood pressure and CHD, it has not been shown that omega-3 fatty acids specifically affect blood pressure in normal subjects in a way that would provide a protective benefit toward the risk of CHD. Effects of omega-3 fatty acids on other markers linked with CHD, e.g., fibrinogen or lipoprotein (a) have not been established.

(56 FR 60663 at 60671).

a. Atherosclerosis

i. Blood lipids

30. Numerous comments criticized FDA's focus on blood cholesterol as a surrogate marker for risk of CHD, although one comment noted that such an emphasis would be expected, given the importance of cholesterol in CHD. Another stated that the focus on cholesterol ignores other factors that determine blood cholesterol such as heredity, exercise, and stress, etc.

FDA disagrees with the comments that it overemphasized the importance of studies in which cholesterol was measured as a surrogate marker for CHD. The considerable attention given to blood cholesterol measurements (and measurements of other blood lipids and the protein components of blood lipoproteins) was the consequence of two factors: (1) There was a large number of studies on the effects of fish oils or fish containing omega-3 fatty acids on these blood lipid measures; and (2) there is general agreement that certain blood lipids are strongly associated with the risk of CHD.

FDA undertook to evaluate findings in these studies whether or not fish or fish oils were used as the source of omega-3 fatty acids and whether or not the outcome measures were generally recognized as predictive of CHD. This approach allowed the identification of biologic activities of omega-3 fatty acids that may be related at some point to risk of CHD, and identified areas where additional research is needed. FDA included in the summary of its proposed rule (56 FR 60663) only measures of generally recognized risk factors. FDA did not intend to imply that data on alternate markers were not considered in its decision.

FDA agrees that other factors contribute to blood lipid measures, but believes that randomization should control for these factors. In nonrandomized studies, these sources of potential bias limit the conclusions that can be inferred from the data. This is an important reason that data from correlation studies do not conclusively establish a relationship between omega-3 fatty acids and risk of CHD.

31. The LSRO report paid considerable attention to changes in blood lipids after increased consumption of omega-3 fatty acids, and reached some conclusions about effects of omega-3 fatty acids on blood lipids that differed from those reached by FDA. LSRO abstracted three studies from before the period covered by FDA review (Refs. 284a, 267, and 257). These studies were considered in Federal Government and other comprehensive reports reviewed in the proposed rule and not discussed further by FDA. LSRO also included three studies not reviewed by FDA in its proposal (Refs. 168, 226, and 301). Agren et al. (Ref. 168) studied healthy students randomly assigned to their normal diet (one fish meal per 2 weeks), a fish diet, or a fish diet low in saturated fat for 15 weeks. There was no change in total serum cholesterol on the control diet or fish diet, but the low-fat fish diet produced a reduction in total cholesterol. Jensen et al. (Ref. 226) studied 18 healthy subjects supplemented sequentially for 4-week periods with 4-week washouts between, with fish oils containing 1, 3, and 6 g EPA plus DHA, and found no change in total or LDL cholesterol. Wolmarans studied healthy subjects fed a meat diet or fish diet containing 6.1 g EPA plus DHA for 6 weeks each in a crossover design, and found reduced total cholesterol and LDL cholesterol during the fish diet phase. There was no difference in total fat of the two diets. However, there was significantly less saturated fat in the fish diet, so it is not certain that the omega-3 fatty acids were responsible for the decrease in the cholesterol measures.

FDA is concerned that the studies abstracted by LSRO do not accurately represent the totality of publicly available scientific evidence. For example, in its proposal, FDA included five studies among normal subjects (Refs. 2, 6, 24, 73, and 143) and three studies among subjects with preexisting lipid or lipoprotein abnormalities (Refs. 18, 73, and 93) not included in the LSRO report that had data for effects of omega-3 fatty acids on plasma lipids or lipoproteins. FDA determined that seven studies that reported changes in total cholesterol had the most rigorous designs and the largest numbers of normal subjects. None of these seven studies (Refs. 6, 9, 14, 49, 54, 73, and 166) in normal subjects found a significant change in total cholesterol after fish oil supplementation. FDA found similar results with regard to hyperlipidemic subjects.

Only two of these seven strongest studies in normal subjects were abstracted in the LSRO text, and two others were not cited at all by this report. LSRO did not distinguish between normal and hyperlipidemic subjects in its summary or conclusions. LSRO summarized the evidence on total cholesterol by stating, "Decreases in total cholesterol * * * have *also* been reported," (emphasis added), without mentioning that the predominant finding is that there is no effect on total cholesterol.

Similarly, FDA stated that the strongest studies among normal subjects (Refs. 6, 9, 14, 49, 54, 73, and 166) found no change in LDL cholesterol, and one reported an increase in LDL cholesterol (Ref. 54). Indeed, most studies on hypertriglyceridemic or hypercholesterolemic subjects reported an increase in LDL cholesterol following fish oil supplementation (56 FR 60663 at 60669). Consequently, FDA disagrees strongly with the summary statements in the LSRO report:

> Effects of fish oil upon LDL have been variable, in part because of different doses. In normolipidemic individuals, LDL has generally declined significantly. In *some* patients with primary hypercholesterolemia, consumption of fish (sic) has not resulted in altered plasma cholesterol levels; other studies have shown decreased cholesterol and LDL levels. (Emphasis added.)

32. Two comments stated that FDA had not considered all relevant data on HDL_2 cholesterol, and cited additional

studies that reported increased HDL_2 cholesterol after fish oil supplementation. One comment stated that overall HDL cholesterol tends to rise, and cited a review paper by Harris (Ref. 62). The LSRO report also concluded that HDL was increased by fish oil supplementation.

FDA disagrees with the comment regarding the overall HDL cholesterol change after fish oil supplementation. The agency considered HDL changes separately for normal, healthy subjects and for hyperlipidemic subjects (56 FR 60663 at 60669). Nearly all studies on normal subjects found no significant change in HDL cholesterol level. Some investigators reported increased HDL_2, but the data on HDL_2 were equivocal.

FDA also disagrees with the conclusions of the LSRO report regarding HDL cholesterol, because it does not represent the totality of publicly available scientific evidence. The LSRO summary states, "In *some* studies HDL concentrations have actually increased with consumption of fish oil" (emphasis added), not acknowledging that the balance of available scientific evidence on HDL indicates no change. In the review by Harris cited in the comment, the changes in HDL cholesterol in each study were weighted according to the number of subjects in the study, giving a per-subject change. This method of pooling data from different studies does not account for the variation of the response of subjects in each study, the amount of omega-3 fatty acids fed, the duration of feeding, or the source of the omega-3 fatty acids. Therefore, it must be considered only an estimate of the effects of omega-3 fatty acids on HDL cholesterol. Harris calculated the average HDL cholesterol change for normal subjects to be an increase of approximately 3 percent, a net change smaller than the usual variability in the test used to measure HDL.

The agency agrees with the comment that not all HDL_2 data were considered in the proposed rule, although FDA noted (56 FR 60663 at 60669) that some studies among normal subjects found increases in the HDL_2 fraction of HDL cholesterol, and that these reports were the most promising changes in blood lipids. Of the six references cited by the comments as not included among studies showing increased HDL cholesterol after omega-3 fatty acids, two were published after the time period covered in the proposed rule (Refs. 235 and 252). One other paper not cited by FDA in its proposal, although it was published during 1988 (Ref. 291), dealt with insulin-dependent diabetics. The other three papers were cited by FDA in other contexts, but data from these papers regarding HDL_2 cholesterol levels were not discussed (Refs. 1, 32, and 148).

FDA reexamined those papers that it cited but from which it did not present data regarding HDL_2, together with the newer papers. When fractions of HDL cholesterol have been reported, an increase has generally been found in the HDL_2 fraction (Refs. 1, 32, 148, 235, 251, and 291), with a comparable decrease in the HDL_3 fraction (Refs. 1, 235, and 251). This represents a shift within the HDL fractions toward a lipid-rich lipoprotein, and away from a protein-rich lipoprotein, similar to that reported for LDL, below. This shift has been reported when there is (Refs. 32, 148, 235, and 291) or is not (Refs. 1 and 251) a change in total HDL cholesterol. This raises the possibility that a shift occurred in other studies where total HDL was reported as not changed.

However, the importance of the shift in subfractions of HDL is not clear. FDA noted in its proposal (56 FR 60663 at 60669) that there is evidence that the HDL_2 fraction is the one most closely linked to risk of CHD. However, the agency was unable to find evidence that there was significant scientific agreement that HDL_2 was the fraction of HDL most closely associated with CHD. The National Institutes of Health's National Heart, Lung, and Blood Institute (NHLBI) consensus development conference on Triglyceride, High Density Lipoprotein and Coronary Heart Disease (Ref. 255), anticipated in the proposal (56 FR 60663 at 60664), concluded that, "It is not known to what extent these alterations of HDL contribute to atherogenesis."

Therefore, data on changes in HDL subfractions after increased consumption of omega-3 fatty acids do not provide a sufficient basis for a health claim, because there is not significant scientific agreement that HDL_2 is directly related to risk of CHD. If the risk of CHD becomes linked with HDL_2, these findings in normal subjects may be of great importance.

33. Many comments indicated that high triglycerides are causally related to decreased HDL, that triglycerides are an independent risk factor for CHD, or that statistical manipulations of data and imprecise measurements of triglycerides obscure the importance of triglycerides as a risk factor for CHD. One comment provided additional citations regarding the relationship between triglycerides and HDL, but these did not bear on risk of CHD. One comment stated that it was generally agreed that triglycerides were not independently associated with CHD.

FDA disagrees with all but the last comment. FDA is aware that there has been, and still is, substantial interest in the potential role of triglycerides in the etiology of CHD (e.g., Ref. 208). Because of the continued interest, the relationship between triglycerides and CHD was the topic of a consensus development conference sponsored by NHLBI on February 26 through 28, 1992. NHLBI had previously addressed this topic in 1983 and concluded at that time that the relationship was controversial. The recent conference (Ref. 255) concluded, "For triglyceride, the data are mixed; although strong associations are found in some studies, the evidence on a causal relation is still incomplete."

FDA agrees that the statistical methods previously used to study the relationship between triglycerides and CHD have lessened the likelihood that triglycerides would be found to be a significant, independent predictor of CHD. Furthermore, the agency believes that study design and analytic measurement methods have contributed to variation in triglycerides that may have resulted in reducing the statistical association between triglycerides and CHD. FDA believes that these sources of variation in triglycerides can be reduced by careful study design and standardized analytical measurement techniques, and also that clinical studies designed to lower triglycerides could provide a basis upon which to reconsider the importance of triglycerides in CHD.

34. Some comments stated that some very recent evidence from the Helsinki Heart Study supports a protective effect of lowering triglycerides, at least for a selected subpopulation of people with a high ratio of LDL cholesterol/HDL cholesterol and very high triglycerides.

FDA agrees that fish oils reduce plasma triglycerides. In its proposal FDA wrote, "The predominant blood lipid effects of fish oils * * * are decreased plasma triglycerides and VLDL." (56 FR 60663 at 60669.) In this regard FDA and LSRO were in agreement. The LSRO summary states, "The most striking effect is lowering of plasma triglyceride and VLDL concentrations."

FDA disagrees, however, that triglycerides have been established as an independent risk factor for CHD. The recent results from the Helsinki Heart Study (Ref. 242) were discussed at length at the NHLBI consensus development conference (Ref. 255). While the reduction in CHD mortality following drug intervention was dramatic (i.e., approximately 7-fold) for a particular subgroup with both elevated

triglycerides and elevated LDL to HDL ratio, this result was obtained by a post hoc analysis of earlier results. Because the combination of factors used to connote the high-risk group (i.e., high LDL cholesterol to HDL cholesterol ratio *and* high triglycerides) was determined after the data were collected, these results are not the results of the testing of a hypothesis, but are the origins of a new hypothesis. The authors indicate that the cut-off points for the ratio of LDL to HDL and triglycerides chosen were to some extent arbitrary. The actual number of cardiac events in the study was small (e.g., 18 events among 138 subjects in the highest risk subgroup), and the reduction in all-cause mortality due to the lipid-lowering drug, gemfibrozil, was not significant. Finally, independent of LDL to HDL ratio, increased triglycerides alone were not associated with an increased risk of heart attack.

The dramatic reduction of triglycerides by omega-3 fatty acids has resulted in their use in the treatment of a rare genetic hypertriglyceridemia (type V) to prevent noncardiovascular effects of high triglycerides (i.e., pancreatitis), but the usefulness of lowering triglycerides as a general strategy in prevention of CHD is not generally agreed. Therefore, FDA believes that the triglyceride-lowering effect of fish oils for some at-risk persons does not provide a basis for a health claim at this time.

35. Numerous comments indicated that postprandial triglyceridemia is a mechanism of action in the development of atherosclerosis. Some comments indicated that the relationship of elevated triglycerides to risk of CHD would be discussed at the NHLBI consensus development conference (Ref. 255). Others pointed out that LSRO had concluded that elevated very low density lipoproteins (VLDL) and triglycerides were atherogenic. LSRO stated that the reduction of postprandial hyperlipidemia is a "most important anti-atherogenic action." LSRO wrote in the summary that, "Since postprandial lipemia has been identified as an atherogenic risk factor, its prevention by w-3 fatty acids *would be* a most desirable effect" (emphasis added), and in its conclusions LSRO wrote:

> Fish oil has a generally accepted hypolipidemic effect without depressing HDL. This applies most to VLDL and triglyceride, lipids now believed to be atherogenic. There is little doubt that there is a reduction of postprandial hyperlipidemia following the ingestion of dietary fat if the background diet contains relatively small quantities of w-3 fatty acids. This may be a most important anti-atherogenic action.

FDA agrees that fish oils do not generally lower HDL. FDA also agrees that major blood lipid effects of omega-3 fatty acids are reductions of triglyceride and VLDL. The role of omega-3 fatty acids in the reduction of postprandial triglycerides was described in three papers abstracted by LSRO (Refs. 15, 59, and 163). While the first two papers used high levels of omega-3 fatty acids (30 and 9 g of EPA plus DHA/day, respectively), the recent paper used only 5 g of fish oil, containing 1.7 g EPA plus DHA. These studies showed that the concentration of plasma chylomicrons after a high-fat test meal was significantly less if the subjects had been consuming a fish oil diet than if they had been consuming a saturated fat or olive oil supplemented diet. Thus, FDA agrees that fish oils reduce postprandial lipemia.

However, FDA disagrees that there is significant scientific agreement that VLDL and triglycerides are atherogenic, or that the reduction in postprandial hyperlipemia is a most important anti-atherogenic action. Neither the Federal Government nor other authoritative reports have included these blood lipid measures among those they consider to be independent risk factors associated with CHD (Refs. 34 through 36, and 115). Furthermore, postprandial lipemia was discussed at the February 1992 NHLBI consensus development conference. The summary of that conference stated, "Postprandial triglyceride may be more important than the fasting triglyceride levels [to CHD], but little is known about this at the present time." (Ref. 255).

FDA notes that the only paper in the LSRO report cited in support of this hypothesized mechanism of action of omega-3 fatty acids in the prevention of CHD was a review paper published in 1979 (Ref. 305). Therefore, FDA believes that there is not significant scientific agreement at this time that postprandial triglycerides are related to the risk of CHD.

ii. Vessel wall effects

36. One comment indicated that two new studies support the use of omega-3 fatty acids to prevent restenosis, the closing of a mechanically opened blood vessel (Refs. 172 and 259). This comment suggested that FDA discounted the findings of the Dehmer study (Ref. 30) on the basis that it employed simultaneous treatment with drugs and fish oils.

FDA considered the use of omega-3 fatty acids to prevent restenosis to be a drug usage (56 FR 60663 at 60670), and notes that patients in these studies are under a physician's care. FDA's description of the Dehmer study points out a limitation of the data that is common in other reports of no effect of omega-3 fatty acids in restenosis (Refs. 56, 106, and 121), that the studies have not controlled for generalized effects of PUFA's that are not specific to omega-3 fatty acids. A better balanced experimental design would be comparison of drugs plus omega-3 fatty acids to drugs plus alternate PUFA's (e.g., corn oil).

FDA agrees that the new studies provide some support for the role of omega-3 fatty acids in prevention of restenosis, although neither was designed to distinguish effects of omega-3 fatty acids from effects of omega-6 PUFA's.

Nye et al. (Ref. 259) studied 79 men and 29 women who were referred for angina and underwent coronary percutaneous transluminal angioplasty (PCTA), i.e., a mechanical opening of a closed heart blood vessel. The subjects were randomly assigned to one of three treatments: (1) A combination of aspirin plus dipyridamole (an anti-platelet combination of drugs), (2) olive oil placebo, or (3) 12 milliliters (mL) fish oil containing 3.2 g EPA plus DHA/day. Subjects were restudied 1 year later or before if symptoms recurred, and 93 percent of all subjects were followed for the year. Although there was no significant difference in angina among the groups, the rate of restenosis, defined in this study as a loss of 50 percent or more of the luminal diameter increased by PCTA, was significantly less in the fish oil group (11 percent) than in the placebo group (30 percent).

The use of olive oil as the placebo did not control for effects due to PUFA's (omega-6). Also, it is notable that the restenosis rate in the aspirin group was somewhat higher (17 percent) than in the fish oil group, because aspirin is a much more potent inhibitor of platelet function than EPA in fish oil. Nonetheless, these results are consistent with an effect of omega-3 fatty acids in reducing restenosis.

The full "Quebec study" was published after the receipt of the comment, but because it was cited in the comment it will be discussed here. In this study, Bairati et al. (Ref. 172) conducted a double-blind, randomized intervention with either fish oil containing 4.5 g EPA plus DHA/day, or olive oil placebo in 205 patients undergoing first PCTA. The treatments were started 3 weeks before the procedure, and continued for 6 months after. Restenosis was assessed angiographically, using a quantitative

computer analysis program. Restenosis was reduced in the fish oil group compared to the olive oil group according to 3 of 4 definitions of restenosis. It was not reduced according to the clinical definition used by Nye et al. (Ref. 259), above, of a loss of 50 percent or more of the luminal diameter increased by PCTA.

This study also collected dietary data. The third of the subjects with the highest consumption of omega-3 fatty acids (0.15 g/day) and the third of the subjects with intermediate consumption of omega-3 fatty acids (0.033 to 0.15 g/day) had significantly lower rates of restenosis than the third consuming the least amount of omega-3 fatty acids. In fact, dietary omega-3 fatty acids (other than the supplement) were associated with a greater reduction in chance of restenosis than was the supplement. This result was somewhat surprising, since the supplement contained 30 times the amount of omega-3 fatty acids in the diet. No differences in rate of restenosis were found according to intake of total fat, polyunsaturated fat, monounsaturated fat, saturated fat, cholesterol, or total seafood consumption. These results suggest that chronic consumption of low amounts of omega-3 fatty acids may be as useful in preventing restenosis as much larger amounts consumed for a few weeks prior to and after PCTA.

In general, the results of Bairati et al. (Ref. 172) and Nye et al. (Ref. 259) are consistent, even though they obtained different results according to one identical definition of restenosis. The Bairati et al. study, like Nye et al. 1990, used olive oil as the control. If the mechanism of action of omega-3 fatty acids in restenosis is through competition with AA, this control is suitable, and an omega-6 fatty acid oil would have made the difference due to omega-3 fatty acids even more pronounced. If, however, the mechanism of action is through nonspecific effects of highly unsaturated fatty acids, then a control of a PUFA (e.g., corn oil) might have reduced the apparent effect of omega-3 fatty acids. It is notable that the only study of restenosis that has used a polyunsaturated fat control (an olive oil-corn oil mix) did not find an effect (Ref. 56).

37. Five studies in humans relevant to the actions of omega-3 fatty acids on the vessel wall were referenced in comments (Refs. 200, 213, 259, 268, and 277), including two published since the time period covered by FDA's review in its proposed rule (Refs. 200 and 268). Hamakazi et al. (Ref. 213) found a slower aortic pulse wave velocity (an electro-physiologic measurement) in persons from a Japanese fishing village compared to those from a farming village. Other data showed the populations differed in their intake of omega-3 fatty acids. Rapp et al. (Ref. 268) measured the amount of omega-3 fatty acids in the atherosclerotic lesion after consumption of omega-3 fatty acids at a high level (6 percent of calories, 16 to 21 g EPA plus DHA/day) for 6 to 120 days prior to planned surgical intervention, and found that the amount of omega-3 fatty acids in the lesion continued to increase throughout the time of ingestion. Force et al. (Ref. 200) studied the effects of fish oils and aspirin on the production of urinary metabolites of AA and EPA. Fish oil feeding resulted in a slight decrease in the amount of thromboxane A_2 made in the platelet, a decrease in the amount of AA-derived prostacyclin made in the endothelial cell, and an increase in the amount of EPA-derived prostacyclin made in the endothelial cell. Schmidt et al. (Ref. 277) described decreased monocyte chemotaxis among hypertensive patients after fish oil feeding. The Nye et al. study is discussed in comment 36 of this document.

FDA considers these studies to be observational, not clearly associating omega-3 fatty acids with risk of CHD. The correlation data of Hamakazi et al. do not indicate a specific role for omega-3 fatty acids. The Rapp et al. data verify that it is possible to incorporate omega-3 fatty acids into preexisting atherosclerotic plaque, but the relevance of incorporated omega-3 fatty acids has not been established. The studies of Force et al. and Schmidt et al. relate to a potential mechanism of action of omega-3 fatty acids, but the importance of these actions in reducing risk of CHD has not been established.

38. Many comments stated that the biochemical and physiological actions of omega-3 fatty acids are anti-atherogenic because they favor vasodilatation and inhibit vasoconstriction. One comment by a manufacturer of omega-3 fatty acids considered these actions have potential for future significance. Two comments cited a list of effects of omega-3 fatty acids, suggesting that each of the effects in the list was anti-atherogenic, and other comments referred to one or more of the components in the list. The listed changes were:
decreased thromboxane;
increased prostacyclin and leukotriene (LTB_4);
decreased fibrinogen;
decreased platelet activating factor (PAF);
decreased platelet-derived growth factor (PDGF);
decreased superoxide;
decreased interleukin-1 (TNF);
increased endothelium-derived relaxation factor (EDRF);
decreased lipoprotein (a) (Lp(a));
reduced inflammatory response; and
increased fibrinolytic activity.

The LSRO report stated that other mechanisms, such as cellular growth factors, interleukin-1 and cytokins, and EDRF may be important in the development of atherosclerosis, and be affected by omega-3 fatty acids. However, except for a single in vitro study on PDGF, no data are described in the report regarding these factors, nor is their relevance to human CHD discussed.

FDA addresses fibrinogen, Lp(a), and fibrinolytic activity in comment 46 and in section II.C.2. of this document. FDA does not agree that omega-3 fatty acids produce changes in all of the listed parameters. FDA has determined that for some of these endpoints the changes have not been shown to be specific to omega-3 fatty acids, but may be due to polyunsaturated fats instead. FDA disagrees that the changes brought about by omega-3 fatty acids will prevent atherosclerosis. Most of the data regarding changes in these endpoints brought about by omega-3 fatty acids have been derived from tissue culture or animal experiments, and the relevance to human atherosclerosis has not been demonstrated.

Thromboxanes and prostacyclins are compounds derived from omega-3 fatty acids and omega-6 fatty acids that affect the relaxed state of the blood vessels. Thromboxanes are produced primarily in platelets, and prostacyclins are produced primarily in the endothelial cells of the blood vessels. The thromboxane made from an omega-6 fatty acid called AA, thromboxane A_2, is a potent vasoconstrictor. EPA competes with AA for the enzyme that makes thromboxane A_2, and thereby diminishes the rate of production of thromboxane A_2; the thromboxane made from EPA is a much less potent vasoconstrictor. The prostacyclins made from AA or EPA in the endothelial cells are vasodilators. Thus, the relative amounts of AA and EPA in platelets and endothelial cells play a role in determining the form and amounts of the prostaglandins and thromboxanes that affect the tension of the vessel wall. Excessive constriction may lead to an occlusion, resulting in a heart attack. While there is general recognition that these vasoactive compounds may play a role in the formation of clots and thereby in heart attacks, there is no

agreement about the extent of changes needed in the concentrations of the vasoactive compounds in order to have an effect on heart disease. Changes in the amounts of these vasoactive compounds, produced by consumption of fish oil, are only useful as marker for CHD only insofar as there is significant scientific agreement that the magnitude of the changes is related to CHD. FDA is not aware of any such agreement, nor did the comments provide any evidence of agreement that particular changes in the levels of these vasoactive compounds were related to a reduction in risk of disease. Furthermore, the amount of omega-3 fatty acids needed to produce these changes in humans is not known.

For PDGF the evidence is confined to animal studies (Ref. 201), and the relevance to human disease has only been suggested, not demonstrated. The animal studies on PDGF also did not show that the effect was specific to omega-3 fatty acids. For example, the PDGF effect was observed also after polyunsaturated fats, and was abolished by anti-oxidants, suggesting that any highly unsaturated fatty acids prone to oxidation would have the effect. The experiments on EDRF (Ref. 181) also did not show that the effects were specific to omega-3 fatty acids, since the experiments were carried out in the presence of indomethacin, which blocks the eicosanoid effects of EPA. In fact, the authors consider changes in membrane fluidity to be a reasonable explanation for the effects. In yet other cases, e.g., TNF, there are conflicting results depending on the species (Refs. 41 and 236), and the findings must be considered preliminary.

FDA considered the effect of omega-3 fatty acids on chemotaxis, one aspect of inflammatory response (56 FR 60663 at 60670). A complete discussion of the role of fish oils in inhibition of the inflammatory process is outside of the scope of this rulemaking, but the relationship between omega-3 fatty acids and inflammatory response could be the subject of a petition for a health claim that includes the necessary information about this relationship.

FDA agrees that the biochemistry of the products formed from the omega-3 fatty acids in vivo (i.e., eicosanoids) have been shown under experimental conditions, usually in vitro, to have pronounced effects on the vessel wall. However, demonstration of isolated biochemical effects is not a sufficient basis upon which to make a claim regarding the outcome of a multifactorial process. Intermediate markers of CHD are useful only insofar as there is significant scientific agreement that changes in these markers produced by omega-3 fatty acids are causally related to CHD.

b. Thrombosis and hemostasis

39. A few comments stated that the mode of action of omega-3 fatty acids may be through stabilization of arrhythmia, and noted the reduced rate of death after heart attacks (MI's) in the Dart study (Ref. 16). This comment also stated that certain animal data were consistent with this hypothesis. The comments stated that the fibrillation mechanism suggested by DART was compelling, because 60 percent of sudden deaths are caused by ventricular fibrillation following reperfusion. Many commented that data from nonhuman primate models show that omega-3 fatty acids abolish arrhythmias, whereas polyunsaturated fat (safflower oil) had a lesser effect.

FDA disagrees with these comments. FDA's review of the literature regarding the usefulness of omega-3 fatty acids in arrhythmia and ventricular fibrillation found only one study on arrhythmias in humans, and it reported no significant effect of omega-3 fatty acids (Ref. 58). A review in 1989 also concluded that, even among the animal studies, there was no significant difference between omega-3 fatty acids and other polyunsaturated fats on arrhythmias (Ref. 269).

The data from the studies in nonhuman primates (i.e., the marmoset monkey) were published only as a nonpeer-reviewed paper in a book (Ref. 188). Two papers by the same author on the same topic were cited in 1990 as in press in a peer-reviewed journal, but have not yet been published. Therefore, FDA regards the data on nonhuman primates as preliminary only. Furthermore, the data for the marmoset monkey were obtained after prolonged feeding for 12 or 24 months with a supplement of DHA-rich fish oil at a level of 8 percent of the diet by weight. FDA calculates that this would provide 2.5 g of omega-3 fatty acids from fish oil/kilogram (kg), over 50 times the usual rate of supplementation in human studies (10 g fish oil or 3 g omega-3 fatty acids/day for a 70 kg subject), and over 300 times the amount of omega-3 fatty acids associated with reduced risk of CHD in the epidemiologic literature (Refs. 16, 38, and 87 report 300 to 660 milligrams (mg)/day). Thus, the relevance of these studies to omega-3 fatty acids in the human diet is questionable.

FDA is aware of in vitro data that show a specific protective effect of EPA against toxicity of heart muscle cells in culture. These results provide a biochemical basis for the hypothesized stabilization of cardiac arrhythmias by omega-3 fatty acids. Although this study (Ref. 212) was performed in vitro on heart cells from rats, it showed that the protective effect was specific to omega-3 fatty acids (EPA) because a similar effect was not obtained when a highly unsaturated omega-6 fatty acid (AA) was used instead.

FDA also regards the evidence from the Burr study of reduced death following a heart attack among those men advised to increase fish consumption as consistent with a stabilization of arrhythmias (Ref. 16). FDA agrees that this postulated mechanism of action is of great potential public health significance. However, the agency finds the clinical data available at this time are not in agreement with animal and in vitro data. Because the clinical data are not in agreement with these other types of data and because of the limitations in the animal studies, FDA concludes that there is not sufficient basis for protective effect specific to omega-3 fatty acids on arrhythmias, and, therefore, CHD in humans.

40. One comment criticized the 6-week clinical study by Hardarson et al. that found no effect of omega-3 fatty acids on arrhythmias (Ref. 58), arguing that the time for incorporation of omega-3 fatty acids into heart phospholipids was too short for an effect to be observed.

FDA agrees in part and disagrees in part with this comment. Generally, the time needed for incorporation of omega-3 fatty acids into cellular phospholipids is short; studies in animals show such incorporation in a period of weeks (Ref. 249). In the Hardarson study (Ref. 58), a substantial amount of cod liver oil was fed (20 mL/day) and a 230 percent increase in plasma phospholipid EPA was found. There was no trend toward reduced arrhythmias. Other data, however, show that although plasma phospholipids increase the omega-3 fatty acid content during the first few weeks of supplementation, the incorporation of omega-3 fatty acids in human atherosclerotic plaque continues to increase through 120 days (Ref. 268). Therefore, FDA agrees with the comment the supplementation period in the Hardarson study (Ref. 58) may have been too short to find an effect of fish oils on occurrence of arrhythmias. Also, the agency notes that the absence of a difference in CHD mortality during the first 6 weeks of the Burr study (Ref. 16) is consistent with the hypothesis that prolonged intake of omega-3 fatty acids (longer than 6 weeks) is needed to observe an effect on arrhythmias or

other mechanisms that reduce CHD mortality. FDA agrees that effects of long-term consumption of omega-3 fatty acids on arrhythmias, other platelet or vessel wall functions, and even some blood lipid measures have not been sufficiently studied.

i. Bleeding times

41. Two comments stated that there is no evidence of increased bleeding even among patients who had ingested 6 to 8 g of EPA plus DHA/day and underwent emergency surgery, coronary artery bypass surgery or angioplasty. The comments argued that increased bleeding has not a safety concern.

FDA agrees that there are few reports of excessive bleeding after ingestion of omega-3 fatty acids. However, FDA notes that the cited reports are for subjects with CHD, and evidence of the lack of excessive bleeding complications in this population is not sufficient to assure safety of omega-3 fatty acids in the general population. FDA believes that changes in bleeding due to consumption of omega-3 fatty acids remains a valid safety concern (see comment 52 of this document).

ii. Platelet aggregation

In the proposal, FDA stated:

> The relationship between platelet aggregation and the risk of heart attacks or CHD death in the general population is an important line of evidence that would support drug claims and perhaps health claims for omega-3 fatty acids. Although there is some evidence that changes in platelet aggregation may help prevent second heart attacks * * * it has not been shown that changes in platelet aggregation in the general population will reduce the risk of CHD.

(56 FR 60663 at 60670.)
The agency added: "What has not been established, however, is that platelet aggregation is a bona fide surrogate risk factor for CHD in the general population." (56 FR 60663 at 60672.)

42. Many comments argued that platelet aggregation is completely substantiated as a marker for risk of CHD, based on the results of the Physicians' Health Study (Ref. 66). One comment qualified this conclusion stating that the primary effect of omega-3 fatty acids in vivo was to reduce platelet deposition at sites of aortic lesions.

FDA acknowledges that aspirin studies provide evidence that platelet aggregation is a risk factor for CHD. The effect of aspirin in inhibiting platelet function has been shown. Among persons who have already had an MI, aspirin is effective in preventing a second infarction. FDA has proposed that aspirin be used to reduce the risk of death and/or nonfatal heart attack in patients with previous infarction or unstable angina pectoris as a professional labeling indication (provided to health professionals, but not to the general public), in the tentative final monograph for over-the-counter internal analgesic, antipyretic, and antirheumatic drug products (November 16, 1988, 53 FR 46204 at 46259). However, FDA does not consider the effects of aspirin in the Physicians' Health Study sufficient to establish that dietary omega-3 fatty acids would have the same effect in the general population. The Physicians' Health Study did not evaluate omega-3 fatty acids. The study population was highly selected; the rate of heart attacks was approximately 10-fold lower than in the general population, and cardiovascular mortality was only 15 percent of that expected for the general population of white men of the same age. Also, the results of the Physician's Health Study are not as straightforward as presented in the comments. The chairman of the Physicians' Health Study reported that there was a reduced risk of MI in the aspirin group, predominantly in nonfatal MI, but that there was no significant effect on overall cardiovascular mortality (a 2 percent reduction, not statistically significant) (Ref. 66). In addition, the aspirin group in this study had a greater number of sudden deaths (Ref. 282).

In the other primary prevention trial (Ref. 265), aspirin did not have any significant effect on heart attacks, on stroke, or on total vascular mortality. There was a significant increase in disabling stroke in the group taking aspirin.

On the basis of these studies there has not been an endorsement of the use of aspirin as a prophylactic measure against CHD by the general population by the American Heart Association or by the Canadian Medical Association (Ref. 187). Notably, "1992 Heart and Stroke Facts" published by the American Heart Association (Ref. 169) makes no reference to platelet aggregation as a risk factor for heart attacks (although sticky platelets are mentioned to be a consequence of cigarette smoking in the section on stroke), nor is aspirin discussed as an option for CHD prophylaxis, even though other drug and surgical treatments are discussed.

Therefore, FDA concludes that there is not significant scientific agreement at this time that platelet aggregation is a surrogate marker for CHD in the general population.

43. The LSRO report, submitted as a comment, contained abstracts of 19 studies in humans that contained data regarding changes in platelet function following omega-3 fatty acid consumption. LSRO concluded that omega-3 fatty acids prevented platelet aggregation.

In its proposal, FDA stated: "Platelet aggregation is generally considered to be decreased by fish oil consumption." (56 FR 60663 at 60670.) The agency also stated: "* * * platelet aggregation and function are reduced. However, direct relationships between the changes in * * * platelet function and risk or CHD have not been established." (56 FR 60633 at 60671.) Thus, FDA agrees with the conclusions of LSRO about effects of omega-3 fatty acids on platelet aggregation.

Two of the studies described by LSRO were not considered by FDA in its review, because they were published before 1988, and had been considered by Federal Government and other authoritative reports. One study (Ref. 227) used a large amount of fish oil (50 mL/day) not reasonably related to normal dietary intake. The other study (Ref. 211) involved 13 insulin-dependent diabetics, and therefore is of questionable relevance for the general population.

In its proposed rule, FDA considered 13 of the other 17 studies that were abstracted by LSRO. One of the four studies not addressed by FDA was a study on the effects of added vitamin E to fish oil on fibrinogen and fibrinolysis (Ref. 210). Two papers (Refs. 234 and 244) were published after the time period covered by FDA review. Marckmann et al. (Ref. 244) compared the effects of a fish diet and a lean meat diet on plasminogen activator (t-PA), plasminogen activator inhibitor (PAI–1) and the activity of the inhibitor (PAI–1 activity). Li and Steiner (Ref. 234) described changes in in vitro platelet adhesion after fish oil supplementation. The fourth paper was an uncontrolled observation study that found a high frequency of nosebleeds in adolescents supplemented with fish oils (Ref. 189).

Six other papers on thrombosis were not described in the LSRO text, but were included in the table (Refs. 203, 204, 209, 226, 245, and 254). Of these six, one was not relevant to the nutrient-disease relationship (Ref. 245) because it did not study EPA and DHA. Jensen et al. (Ref. 226) found no significant change in bleeding times in normal subjects after 1, 3, or 6 g EPA plus DHA/day in healthy subjects. Green et al. (Ref. 209) found no change in platelet aggregation or platelet count in 27 hyperlipidemic subjects in a randomized double-blind placebo controlled crossover trial. The treatments were 15 g/day fish oil

containing 4.3 g EPA plus DHA and a 50:50 mix of corn:olive oil, with each treatment lasting 8 weeks, and a 4-week washout between. Blood viscosity was decreased by fish oil. Gazso et al. (Ref. 204) found decreased platelet aggregation in healthy subjects after consumption of EFAmol-marine compared to olive oil in a double-blind randomized crossover study. These results of studies confirm others cited by FDA. The other studies (Refs. 203 and 254) pertained to regulators of bleeding and are discussed below.

Eight papers on platelet function were reviewed by FDA but not by LSRO (Refs. 2, 6, 18, 24, 73, 93, 131, and 143). Three studies were uncontrolled (Refs. 18, 93, and 143), while two were randomized (Refs. 2 and 131). Three were randomized, double-blind, placebo-controlled trials that used saturated vegetable oil (Ref. 6), vitamin E (Ref. 24) or wheat germ oil (Ref. 73) as the placebos. The two studies that used vegetable oil or vitamin E as controls found a reduction in platelet aggregation after omega-3 fatty acids, where no difference was reported in the trial that used a wheat germ oil placebo, although the data were not provided in this paper.

FDA and LSRO reached the same conclusions with regard to the effects of omega-3 fatty acids on platelet function. LSRO also concluded that platelet survival is also enhanced, but the only two studies published since 1987 that reported increased platelet survival (Refs. 94 and 144) were both uncontrolled, so the effect cannot be attributed specifically to omega-3 fatty acids.

44. One comment agreed in principle with the agency's assessment of the effects of omega-3 fatty acids on bleeding times, platelet aggregation, regulators of bleeding and blood pressure. The comment pointed out the extent of inhibition of platelet adhesion is as much as 60 percent, a marked reduction in adhesion.

FDA agrees that the reported extent of reduction of platelet adhesion from omega-3 fatty acid intake is remarkable (Ref. 234). The agency notes that this effect appears specific to omega-3 fatty acids at reasonable intake levels. FDA notes that animal studies (Refs. 230 through 233) published since the proposed rule provide evidence of reduced platelet adhesion to blood vessel endothelium in vivo in response to agents that provoke such adhesion. Because of the magnitude of the effect of omega-3 fatty acids on platelet adhesion, FDA considers this action of omega-3 fatty acids on blood platelet function to have great potential with regard to the development of atherosclerosis and the risk of CHD. However, as for platelet aggregation, FDA does not believe that there currently is significant scientific agreement that platelet adhesion is an accepted risk factor for CHD in the general population.

iii. Regulators of bleeding

In its proposal (56 FR 60663 at 60670 through 60671), FDA reviewed data on the effects of omega-3 fatty acids on other factors that are involved in the regulation of bleeding—fibrinogen, fibrinolytic activity and Lp(a)—and that have been associated with CHD.

45. Some comments, including the LSRO report, stated that omega-3 fatty acids increase fibrinolysis.

FDA disagrees with these comments. FDA found that there was no clear relationship between omega-3 fatty acids and factors involved in dissolving blood clots (56 FR 60663 at 60671). FDA noted that the data did not establish that omega-3 fatty acids reduced fibrinogen, because most studies did not control for other factors that might have reduced fibrinogen, e.g., other PUFA's.

FDA has reviewed the relevant studies again, as well as studies brought to its attention in the LSRO report. LSRO cited three papers on fibrinogen or fibrinolysis not cited by FDA. One placebo (vitamin E) controlled study found no change in fibrinolytic activity (Ref. 210). Mullertz et al. (Ref. 254) supplemented seven healthy adults with 0.55 g EPA plus DHA/day for 21 days and found increased levels of PAI–1, but no change in t-PA, suggesting that fish oil decreased fibrinolytic capability. Gans et al. (Ref. 203) reported no change in fibrinogen concentration after EFAmol-marine compared to corn oil, which is rich in polyunsaturated fat. These studies do not support the conclusion that omega-3 fatty acids reduce fibrinogen, or increase fibrinolysis.

The selection of studies abstracted by LSRO may not have represented the publicly available scientific evidence. For example, five papers abstracted found either a decrease in fibrinogen or an increase in fibrinolytic activity (Refs. 57, 71, 98, 104, and 117). In contrast, two studies found no change in fibrinolytic activity (Refs. 150 and 166), and only one found increased fibrinogen (Ref. 144), leaving the impression that omega-3 fatty acids usually have been reported to enhance fibrinolysis.

However, three other studies not abstracted by LSRO but included in their tables reported no effect of omega-3 fatty acids on fibrinogen compared to corn oil (Refs. 10, 118, and 203). One found a decrease compared to olive oil (Ref. 49) and one found a decrease compared to soybean oil only when 30 mL of fish oil were consumed, but not when 15 mL were consumed (Ref. 57). Additional well-designed studies not cited by LSRO, but considered in the FDA proposal, reported no change (Ref. 24) and an increase (Ref. 131) in fibrinolytic activity.

Therefore, FDA stands by its earlier conclusion that the publicly available scientific evidence does not support a relationship between omega-3 fatty acids and decreases in fibrinogen or increases in fibrinolysis. This conclusion is supported by findings that consumption of other PUFA's have effects comparable to those produced by consumption of omega-3 fatty acids.

46. Two comments cited unpublished data by Kostner and Herrmann, reporting reduced Lp(a) after fish oil consumption.

FDA was unable to find the full paper by these authors showing the decrease in Lp(a). FDA did find a paper by these researchers published in 1991 (Ref. 241) that reported no effect of fish oils on Lp(a) and did not cite conflicting work from their laboratory.

iv. Blood pressure

In its proposal, FDA considered the relationship between omega-3 fatty acids and blood pressure, one of the recognized risk factors for CHD. FDA stated:

> These results for effects of omega-3 fatty acids on blood pressure of normal subjects are ambiguous. Some studies found a reduction in systolic blood pressure after consumption of fish oils containing omega-3 fatty acids, whereas others did not. None of the studies found a significant reduction in diastolic blood pressure. Therefore, it also remains to be established that the normal, healthy population will reduce their risk of CHD via a reduction in blood pressure following consumption of omega-3 fatty acids.

(56 FR 60663 at 60671.)

FDA also stated that it was not known whether or not the magnitude and duration of the effect would persist after longer term supplementation. FDA recognized that studies among hypertensives found an effect more consistently than studies among normal subjects, although sometimes large amounts of fish oils were used.

47. Some comments considered the effects of omega-3 fatty acids on hypertension as evidence of a reduction in CHD risk. Other comments called for FDA to reassess the studies on blood pressure. One of these comments argued that the results of studies on blood pressure are not "completely"

ambiguous. One comment agreed in principle with the agency's assessment of the blood pressure studies. One comment considered a number of animal models to be relevant for hypertension. The LSRO report also considered the evidence relating omega-3 fatty acids to blood pressure to be important in relation to CHD. The LSRO report concluded that, "Fish oil probably has a mild hypotensive effect, especially in high doses."

FDA disagrees that the publicly available scientific evidence supports a relationship between omega-3 fatty acids and hypertension. At best, as stated in the proposal, the data are ambiguous. Qualifiers are needed to indicate that the reductions in blood pressure have not generally been shown to be specific to omega-3 fatty acids. Also, many valid studies have reported no effect.

LSRO reported a total of 13 studies on hypertension. Four were published before 1988, and were not reviewed by FDA in the proposed rule. Three of these studies used fish as the source of omega-3 fatty acids and therefore did not show the effect specifically to be due to omega-3 fatty acids. In fact, in one study (Ref. 292), the control diet of meat produced a decrease in blood pressure comparable to that of the fish diet. The study that used fish oils (Ref. 271) used an olive oil control, rather than an oil high in PUFA's. This study is the only study to show an effect of omega-3 fatty acids on diastolic blood pressure in normal subjects.

Of the other 10 studies on hypertension described in the LSRO report, 6 were also reviewed by FDA (Refs. 11, 57, 80, 85, 95, and 101). The LSRO and FDA interpretations of the results from these papers did not differ in any significant regard, except that FDA specifically noted that two of these studies (Refs. 85 and 95) used very high amounts (50 mL) of fish oil to show the effect. In fact, FDA singled out the Bonaa et al. (Ref. 11) and Kestin et al. (Ref. 80) studies as well-designed studies that showed an effect specific to omega-3 fatty acids in hypertensive and normal subjects, respectively (56 FR 60663 at 60671).

The LSRO report reviewed four papers not originally reviewed by FDA (Refs. 190, 285, and 299), including one study on linolenic acid outside of the scope of the definition of omega-3 fatty acids as used in this regulation (Ref. 262). Two other papers that appeared in the LSRO table but not in the text (Refs. 203 and 247) were also not reviewed by FDA in its proposal.

FDA agrees with the LSRO interpretation of the Wing et al. study (Ref. 299), where subjects remained on blood pressure lowering medications and no effects of added fish oils were observed.

FDA disagrees with the LSRO descriptions of the Singer and Cobiac studies. The placebo in the Singer study (Ref. 285) was olive oil, but this was not pointed out in the LSRO text. The reduction of blood pressure observed after fish oil, therefore, may have been due to a general unsaturated fatty acid effect not specific to omega-3 fatty acids. In the description of the Cobiac et al. study (Ref. 190), LSRO did not note that fish oil treatment alone (without simultaneous reduction of salt) had no effect on blood pressure.

Two other studies were cited in the LSRO tables but not in the text and were not included in the FDA review. Neither of these found an effect on blood pressure. Gans et al. (Ref. 203) used a randomized double-blind, placebo-controlled design and found a reduction in diastolic blood pressure for both fish oil and corn oil (placebo). Meland et al. (Ref. 247) carried out a randomized, double-blind multicenter trial among 40 mildly hypertensive subjects, using 6.8 g EPA plus DHA/day, but found no difference in blood pressure compared to a 50:50 olive:corn oil control.

Three other large and appropriately controlled studies not in the text of the LSRO report but included in its table were also reviewed by FDA. Two randomized studies on normal subjects (Refs. 9 and 49) and one controlled study among mildly hypertensive subjects (Ref. 20) reported no differences in blood pressure attributable to omega-3 fatty acids.

FDA reviewed in its proposal three other randomized, double-blind, placebo-controlled studies among healthy subjects that were not included in the LSRO review. Two of these studies were on normal, healthy subjects (Refs. 6 and 24) and found a decrease in systolic blood pressure compared to a saturated vegetable oil or vitamin E, respectively. The third study (Ref. 73) found that omega-3 fatty acids did not affect blood pressure in hypertensives or normal men compared to wheat germ oil.

Therefore, FDA concludes that the evidence of an effect of omega-3 fatty acids on blood pressure in normal subjects is ambiguous, because some studies reported a blood pressure lowering effect, whereas other equally well-designed studies found no specific effect. Studies among hypertensives found an effect more consistently than studies among normal subjects, although sometimes large amounts of fish oils were used, and many studies did not show that omega-3 fatty acids were more effective than other polyunsaturated fats.

48. Comments stated that other lines of evidence were not discussed in the proposal. Examples given were changes in plasma viscosity, increased vascular compliance, and reduced white blood cell (WBC) count.

FDA disagrees with the comment with respect to plasma viscosity and vascular compliance. In its proposed rule, FDA acknowledged that plasma viscosity was decreased and red cell deformability was increased by omega-3 fatty acids, but that the importance of these effects on the risk of CHD had not been established (56 FR 60663 at 60670).

The agency agrees that it did not systematically consider WBC count among the effects produced by omega-3 fatty acids. WBC count was not included among the actions of omega-3 fatty acids considered in major reviews. FDA notes that WBC count has only recently been identified as associated with risk of CHD by the Caerphilly Collaborative Heart Disease Study (Ref. 301a). Only two papers among literature from 1988 to present have reported a reduction of WBC count after fish oil supplementation (Refs. 183 and 253).

3. Other relevant information

a. Animal studies

49. Numerous comments asserted that animal studies did not receive an appropriate amount of discussion. One of these same comments stated that animal studies are not sufficient to support the claim, and that clinical trials on effects of omega-3 fatty acids directly on CHD are needed. One comment criticized FDA's review of animal studies because the negative findings have been in inappropriate models and should not have been discussed. Another comment stated that they did not believe that there is an appropriate animal model for human cardiovascular and CHD. The LSRO report considered animal studies to provide important evidence for an anti-atherogenic effect of fish oils, stating, "Omega-3 fatty acids have been shown to retard the development of the atherosclerotic plaque in experimental animals including the pig and rhesus monkey."

FDA agrees that the evidence from studies in animals warrants additional discussion. FDA has reviewed here those animal studies that were cited in its proposed rule and those that were cited in the LSRO report that were relevant to the development of atherosclerosis. Other animal studies relevant to the development of

atherosclerosis, and animal studies on aspects of CHD other than atherosclerosis are reviewed under section II.C.3.a. of this document.

In its proposal, FDA cited eight animal studies and one abstract on the development of atherosclerosis that were not included in the LSRO review (Refs. 19, 51, 65, 81, 97, 123, 126, and 151), seven of which reported either no beneficial effect or an adverse effect in fish oil supplemented animals. Only one animal study on the effects of omega-3 fatty acids on restenosis was abstracted by LSRO, although the others cited by FDA were described in the LSRO tables.

Three studies in nonhuman primates have been reported (Refs. 27, 47, and 116). In the Davis et al. (Ref. 27) and Parks et al. (Ref. 116) studies, the polyunsaturated fat intake was higher in the fish oil groups, and polyunsaturated fat is known to lower total plasma cholesterol. Also, the control diet of the Davis et al. study had more saturated fat than the fish oil diet. Thus, the effects on atherosclerosis may not have been specific for omega-3 fatty acids.

In these studies, the total cholesterol values for the fish oil groups were substantially lower than for the control group, which may explain the observed differences in atherosclerosis. In support of this interpretation, Parks et al. (Ref. 116) noted that one of monkeys fed the fish oil diet responded differently than the other 11 monkeys fed fish oil. This one monkey had a plasma cholesterol level comparable to that of the lard-fed control monkeys, and also had atherosclerosis comparable to the lard-fed monkeys.

Changes in total cholesterol levels were noted by authors of another study in pigs that showed a reduction in atherosclerosis concomitant with a reduction in time-weighted total cholesterol (Ref. 81). Since cholesterol concentrations are not changed by fish oils in humans, animal studies where fish oil treatment lowered total cholesterol levels are of questionable relevance to the role of omega-3 fatty acids in the development of human atherosclerosis.

A recent study (Ref. 47) in nonhuman primates (vervet) compared the effects of fish oil supplementation to sunflower oil supplementation in either an atherogenic diet (high fat, low polyunsaturated fat to saturated fat ratio, high cholesterol) or, following the atherogenic diet, in a therapeutic diet (low fat, high polyunsaturated fat to saturated fat ratio and low cholesterol). Animals in each diet group were matched for serum cholesterol. Sixteen separate measures of atherosclerosis were scored, including various measures of the extent of plaque, loss of endothelium, intimal thickening, and inflammation. Overall there was no benefit of fish oil; in some cases, the atherosclerotic measure indicated more disease in the fish-oil fed animals.

The LSRO report considered the amount of fish oil in the diets in this experiment (1.3 to 1.8 percent of calories) too low to observe an effect. In fact, FDA calculates a lower percent of calories from fish oil (1.0 to 1.5 percent) than calculated by LSRO. This level is about half the amount used in short-term human studies (i.e., 10 mL/day), and FDA agrees that the low level makes it less likely that an effect would be observed than if a higher amount had been used. However, diets were supplemented for a prolonged period of time (20 months) and in the therapeutic diet other dietary factors were also changed that might have made the effects of omega-3 fatty acids more noticeable (e.g., ratio of polyunsaturated to saturated fatty acids). Finally, the fact that there were differences between the fish oil-supplemented group and the polyunsaturated fat group while on either the atherogenic or therapeutic regimens suggests that there was sufficient sensitivity in the experimental design to detect protective effects of omega-3 fatty acids.

In some animal studies that showed a protective effect of fish oils, an invasive procedure was used to accelerate atherosclerosis, either mechanical injury (Ref. 122) or vein grafts (Refs. 90 and 186). These studies may be most relevant to the late stages of atherosclerosis, and to CHD in humans following invasive procedures. All of the animal studies cited in the LSRO report except Kim et al. (Ref. 81) and Fincham et al. (Ref. 47) did not control for PUFA's, so the effects observed have not been shown to be specific to omega-3 fatty acids. Additionally, the level of use of fish oils has been high, e.g., 22 percent of calories in Parks et al. (Ref. 116) and 25 percent of the diet in Davis et al. (Ref. 27), which limits the extrapolation of findings in these studies to levels that might be reasonably consumed by humans.

FDA disagrees with the summary of the literature in animals, as expressed in the LSRO report, because that report fails to mention important limitations in the data. FDA notes that most studies did not have an adequate design to show specificity of effects as due to omega-3 fatty acids. Furthermore, reductions in total cholesterol in the fish oil fed animals may explain the reported reductions in atherosclerosis. Since reasonable amounts of fish oils in human diets do not alter serum cholesterol concentrations, the results from these animal experiments are of questionable importance regarding human atherosclerosis. Finally, LSRO did not review numerous animal studies that found no effect or an adverse effect of supplementation with fish oils, and therefore the LSRO conclusion does not represent the totality of publicly available scientific information.

With these qualifications in mind, FDA notes that some of the reported effects of the dietary interventions with fish oils on the development of atherosclerosis have been dramatic. Also, FDA recognized that animal studies are of great importance for study of long-term effects on chronic diseases of consumption of amounts of omega-3 fatty acids, particularly in amounts that might be obtained in a reasonable diet. Therefore, FDA encourages further research in this area using rigorous study designs and amounts of omega-3 fatty acids reasonably available in a normal diet to elucidate any effects specific to these fatty acids.

After closer scrutiny of the animal studies cited in FDA's proposal and in the LSRO report, the agency has reached the same conclusion that it reached in its proposed rule: there are some data in studies from animals which suggest the possibility of a beneficial effect of omega-3 fatty acids on CHD; however, the data are equivocal. (56 FR 60663 at 60671.)

b. Safety considerations

50. One comment stated that the increases in LDL cholesterol observed were a chance occurrence, and another stated that increased LDL should not be considered an adverse finding in light of the results of the Burr study.

FDA disagrees with this comment. FDA found that increased LDL cholesterol was ordinarily found when hyperlipidemics or diabetics were given fish oil supplements. This may be due in part to the fact that fairly large amounts of omega-3 fatty acids (i.e., 5 g EPA plus DHA/day or more) were used in these studies. Increased LDL is not ordinarily seen in the studies on normal subjects.

FDA does not consider the Burr study (Ref. 16) to have established that omega-3 fatty acids reduce the risk of CHD, and therefore remains concerned that increases in LDL cholesterol could be adverse for some subjects. FDA notes that concern about increased LDL cholesterol was expressed in the report of the NHLBI consensus development conference (Ref. 255).

51. One comment stated that it was inappropriate to consider adverse effects

in subpopulations without describing the advantages of omega-3 fatty acids in those same populations.

FDA disagrees with this comment. As noted in the final rule on general requirements for health claims, published elsewhere in this issue of the Federal Register, it would be a violation of the agency's responsibility under the act to authorize a health claim about a substance without being satisfied that the use of the substance was safe. The agency attempted to examine all available scientific evidence regarding the effects of omega-3 fatty acids. FDA separated out the potential adverse effects discovered during its review, because it wanted to draw attention to these issues as impediments to a health claim for omega-3 fatty acids and CHD. Such potential adverse effects must be resolved, and may be important in setting the conditions under which FDA would allow a health claim to appear on the label and labeling of foods and food supplements.

52. Two comments stated that the safety issues raised in the Mitre Corp. report (Ref. 72) were outdated but did not indicate which issues, or suggest why they were outdated.

FDA recognizes that there has been considerable debate regarding the clinical importance of bleeding times since the publication of the Mitre Corp. report (Ref. 72). However, the agency believes that the issues raised in that report have been restated in subsequent literature, and that all issues of safety are important in deciding whether or not to authorize a health claim.

53. A few comments recommended that FDA balance the benefits of reduced risk of CHD against the risk of reduced glycemic control among diabetics when deciding whether or not to authorize a health claim. One comment stated that physicians could adjust the dose of insulin if omega-3 fatty acids reduced their glycemic control, but another comment stated that glycemic control must be considered a real adverse effect.

FDA agrees that limitations on the use of a substance by a subpopulation (e.g., diabetics) do not necessarily exclude a substance from bearing a health claim for the general population, because the claim may be appropriately restricted. However, FDA agrees that the loss of glycemic control is a potentially serious adverse effect that must be fully addressed before a health claim could be authorized.

54. Another comment stated that a major concern about omega-3 fatty acids not mentioned in the proposed rule is that they may be oxidized and, as oxidized products, may have adverse effects.

FDA agrees that oxidation of omega-3 fatty acids is a concern. In fact, there are many studies that have been reported since the publication of the proposed rule, or that were not included in FDA's literature review, that indicate such a concern (Refs. 184, 210, 217, 229, 240, 248, 263, 283, and 290).

Antioxidants have been successfully added to supplements and may be adequate to protect the omega-3 fatty acids in foods. It may be necessary to establish conditions that protect against oxidation of omega-3 fatty acids and incorporate those conditions into any future regulation authorizing health claims for omega-3 fatty acids.

55. A related comment indicated that the majority of the fish oil preparations that have been used are severely oxidized, including National Institutes of Health Fish Oil Test Materials. However, no data regarding the extent of oxidation, the nature of the oxidation products, or the physiologic action of these products was provided.

FDA agrees with this comment. Many of the biologically active products of omega-3 fatty acids are oxidation products. Oxidation of test materials may explain some contradictory findings in the literature.

56. One comment pointed out that increased prothrombin times and possibility of increased stroke were not discussed.

FDA agrees with this comment. FDA did not specifically review data on prothrombin times, although data on bleeding times as a measure of hemostasis were discussed for both normal subjects and for subjects with risk factors for CHD. The importance of the increase in bleeding time brought about by supplemental fish oils or increased fish consumption is not clear. FDA noted in the proposal that most reports suggest that serious bleeding is not an issue in patients supplemented with omega-3 fatty acids, and also that standardized bleeding times do not closely correlate with clinically significant bleeding. However, concerns about untoward bleeding after supplemental fish oils have been raised in the literature (Refs. 106, 120, and 189).

FDA did not discuss the possibility of increased occurrence of stroke as a consequence of increased consumption of omega-3 fatty acids. The papers that reported a correlation between high consumption of omega-3 fatty acids from fish and other marine animals and low rate of CHD mortality also noted an increase rate of stroke, particularly hemorrhagic stroke (Refs. 8 and 84). Also, the possibility of increased rates of stroke are raised by the data from studies on aspirin (Ref. 66).

Thus, FDA considers these potential adverse reactions to be legitimate concerns, primarily in the context of very high intakes of omega-3 fatty acids.

57. One comment stated that even if adverse effects were only suspected in a medical disorder, pronounced warnings or contraindications would be required.

As noted above, the agency must be satisfied that the use of a substance is safe before it will authorize a health claim about the substance. Thus, suspicions about potential adverse effects would need to be resolved prior to the authorization of a claim. Certain health claims may require appropriate qualification as a way of minimizing potential safety concerns.

C. New Scientific Data

To determine whether or not new scientific data published since the proposed rule provided a basis for modifying FDA's conclusions regarding the relationship between omega-3 fatty acids and risk of CHD, FDA conducted a search of the scientific literature for relevant studies. Reviews published since the period covered in the literature review in FDA's proposed rule were used to identify recently published studies.

1. Epidemiologic studies

a. Cross-sectional studies and surveys (Table 1)

Bulliyya et al. (Ref. 185) found lower total serum cholesterol and higher HDL cholesterol in a fish-consuming coastal village population than in a nonfish-consuming population from the interior of India. These correlational data are consistent with a beneficial effect of omega-3 fatty acids on blood lipids, but many possible confounding variables prevent strong conclusions regarding a specific role for omega-3 fatty acids.

In a retrospective study, Popeski et al. (Ref. 266) found that women from communities with higher marine oil consumption had significantly lower diastolic pressure in the last 6 hours of pregnancy than women from communities with low fish oil consumption. Pregnancy associated hypertension was 2.6 times more common in communities with low fish consumption. These correlational data are consistent with an effect of omega-3 fatty acids on blood pressure in this particular situation. Again, many possible confounding variables prevent strong conclusions regarding a specific role for omega-3 fatty acids.

b. Prospective studies (other than intervention studies) (Table 1)

Bjerregaard and Dyerberg (Ref. 176) reported age-standardized mortality rates per 10,000 person-years for CHD in men in Greenland settlements (5.3) as half of that reported for men in Denmark (10.0). There was an increasing rate of CHD from settlements to towns in Greenland. The difference in rates of CHD in women were less apparent, with lower rates in Denmark than in towns in Greenland. These studies do not have sufficient specificity to identify omega-3 fatty acids as causal in reducing CHD, but are consistent with the hypothesis that they are.

Van Houwelingen et al. (Ref. 294) found that, while men from a high fish consumption group had higher concentrations of plasma phospholipid EPA and DHA than men from a low fish consumption group, there was no significant difference in collagen-induced platelet aggregation, cutaneous bleeding time, ATP-release in whole blood, or platelet number between the two groups. This study suggests that the outcome measures found commonly to be affected in clinical studies may not be related to consumption of omega-3 fatty acids in the free-living population.

c. Intervention studies

There were no new prospective intervention studies measuring occurrence of heart attacks or CHD mortality.

2. Evidence relating omega-3 fatty acids to intermediate or surrogate markers of CHD (Table 2) .

a. Atherosclerosis

i. Blood lipids

Through its own literature review, FDA has found another 34 studies not reviewed in the proposal that report data for serum cholesterol after consumption of fish containing omega-3 fatty acids or fish oil concentrated in omega-3 fatty acids. Among these, 25 found no change in blood cholesterol levels, 3 found an increase, and 6 found a decrease.

Studies among normal healthy subjects generally reported no change in total cholesterol (Refs. 168, 196, 202, 210, 217, 220, 235, 241, 253, 254, and 277), although none of these studies was controlled for nonspecific effects of the omega-3 fatty acids as polyunsaturated fats.

One study among normal subjects found that feeding a high fish diet did not change total cholesterol, unless combined with a low total fat and low saturated fat diet (Ref. 168). Another study (Ref. 301) reported decreased total cholesterol after switching from a meat diet to a fish diet, but the fish diet had significantly less saturated fat than the meat diet. One study (Ref. 283) found a slight increase after 5.4 g EPA plus DHA/day from MaxEPA (with 30 percent saturated fatty acids), and one study (Ref. 224) found a slight reduction in total cholesterol after 2.7 g purified EPA/day, but neither study was placebo controlled for effects of polyunsaturated and saturated fat contained in the supplements.

Similarly, nearly all of the 17 studies on subjects in at-risk subpopulations, including all of the studies that controlled for PUFA's (Refs. 203, 209, 247, and 258), found no effect of supplemental omega-3 fatty acids on total cholesterol (except for a post hoc analysis of a subgroup in one study, (Ref. 209)). One study in diabetics (Ref. 252) found an increase in serum cholesterol, but the statistical significance of the result may have been due in part to a change in the opposite direction in the control group. One study among hyperlipidemics (Ref. 191) found decreased cholesterol after relatively high doses (4.6 to 6 g EPA plus DHA/day) but not after 3.6 g EPA plus DHA/day, and did not control for PUFA effects of the supplements. The other study that reported decreased cholesterol after supplemental omega-3 fatty acids (Ref. 268), similarly, found the effect after a high level (6 percent of calories, 16 to 21 g EPA plus DHA/day) and did not control for the polyunsaturated fat effects of the supplement.

These studies support the conclusion reached in the proposed rule, that among normal, healthy subjects there is no significant effect of omega-3 fatty acids from fish or fish oils on total serum cholesterol.

FDA concluded in the proposed rule that the best studies among normal subjects found no effect of fish oils on LDL cholesterol. All of the additional studies among normal healthy subjects obtained in FDA's updated literature search have reported no change in LDL cholesterol (Refs. 220, 253, 253, and 277).

One study (Ref. 224) reported that purified EPA produced a significant decrease in a subfraction of large, light LDL cholesterol (LDL_1), and a significant increase in small, dense LDL cholesterol (LDL_2), but FDA calculates no change for the sum of these two fractions of LDL cholesterol. Some clinical studies reviewed in the proposed rule (Refs. 1, 43, 53, and 129) described changes in the composition of LDL particle after consumption of fish oil.

The relative importance of various subfractions of LDL particles (and the associated composition of the particles), however, is still controversial. While Homma et al. (Ref. 224) suggest that large, light LDL are the fraction associated most closely with atherosclerosis, Austin et al. (Ref. 171) report that the phenotype of small, dense LDL is the fraction most closely related to increased CHD risk. The February 1992 NHLBI consensus development conference (Ref. 255) included among its recommendations for further research the identification of the atherogenic and anti-atherogenic subfractions that may be present in VLDL and HDL; the uncertainty about the relevance of changes in the amounts of subfractions of these two lipoproteins similarly applies to LDL.

In at-risk populations, there have been some additional reports of increased LDL cholesterol after fish oil supplementation (Refs. 170, 191, and 251), a concern raised in the proposal. However, most studies have found LDL cholesterol not changed by fish oils (Refs. 174, 189, 205, 209, 219, 258, and 278). Moreover, each of the studies that used a polyunsaturated fat placebo control group found no change in LDL cholesterol (Refs. 203, 209, and 258).

Therefore, FDA concludes that these most recently reviewed studies support the conclusion reached in the proposed rule, that for the general population, there is no significant effect of omega-3 fatty acids on LDL cholesterol. The results of recent studies among at-risk subjects, however, are not in complete agreement with the conclusions in the proposed rule, and suggest that omega-3 fatty acids may not uniformly increase LDL cholesterol. Additional study is needed to determine the conditions under which LDL cholesterol is increased by omega-3 fatty acids.

Among more recent studies in normal healthy subjects found in FDA's updated literature review, about half have found no effect of fish oils or fish on HDL cholesterol (Refs. 202, 206, 217, 219 (after 1.25 and 2.5 g/day EPA plus DHA), 226 (after 1 and 3 g/day EPA plus DHA), 241, and 244), but about half have found increased HDL (Refs. 210, 219 (after 3.75 and 5 g/day EPA plus DHA), 220, 226 (after 6 g/day EPA plus DHA), 235, 253 (compared to baseline, significant compared to olive oil control), 278, 283, and 301), including a metabolic ward study that very carefully controlled for total fat and saturated fat intake (Ref. 253). Weintraub et al. (Ref. 298) found decreased HDL after fish oil compared to a saturated fat diet.

FDA attempted to ascertain how those studies that reported an increase in HDL cholesterol after increased intake of omega-3 fatty acids differed from those studies in which no effect was found. However, there was no apparent difference between the studies that reported that omega-3 fatty acids reduced HDL cholesterol and those that reported no change. Most of the studies that found a change used supplements containing substantial amounts (e.g., 30 percent) of saturated fatty acids, raising the possibility that the saturated fatty acids in the supplements were responsible for the increase in HDL (Ref. 17). However, some supplements had low amounts of saturated fatty acids (Ref. 278) or saturated fat in the diet was specifically controlled (Ref. 235), and in one study the control diet was reported to have significantly more saturated fat than the fish diet (Ref. 301), so the saturated fat intake during omega-3 fatty acid supplementation cannot be the factor responsible for increased HDL.

The amounts of omega-3 fatty acids used in those studies that reported increased HDL tended to be high (e.g., more than 5 g EPA plus DHA/day), but some studies that found a change used lower amounts (Ref. 278) and some studies that used high amounts found no change (e.g., Ref. 241 (used 6.7 g EPA plus DHA/day) and 253 (used 8 g/day)). Some studies in which fish was fed, rather than fish oil, found an effect (Refs. 235 and 301), but others did not (Refs. 206 and 244). There was no systematic difference in sample sizes of the studies that found an effect and those that did not; seven of the negative studies reviewed in the proposed rule or in the present document had 30 or more subjects, compared to only one of the positive studies. Small studies (n = 10 or fewer) may not have observed a significant difference because of small sample size, but larger studies did not find a significant difference, even though some found a trend toward increased HDL after fish oil supplementation (Ref. 217).

Finally, the enrichment of plasma phospholipids with EPA and DHA tended to be higher for subjects in studies where increased HDL was found than that for subjects in the studies where no change in HDL was found, reflecting the tendency of higher doses to produce increased HDL. In particular, all studies in which the plasma phospholipid EPA value was 3.9 percent or more found increased HDL. However, the studies that fed the highest amounts of EPA but that did not find an effect on HDL did not report data for phospholipid EPA, so it is not clear whether high phospholipid EPA is uniformly associated with increased HDL. Comparable results were found after inspection of data on phospholipid DHA after supplementation, however, because not all studies reported phospholipid fatty acid values, no conclusion can be drawn about the relationship between phospholipid DHA and HDL concentration. Notably, recent data suggest a direct correlation between plasma EPA and HDL, but an inverse relationship between plasma DHA and HDL (Refs. 177 and 178), underscoring the importance of reporting these data in future studies.

Among subjects with risk factors for CHD fewer reports found increased HDL (Refs. 191 (for type IV on SuperEPA only), 195, 203, 209 (for type IIb), and 219) than found no change (Refs. 170, 174, 189, 191 (for type IIb and type IV on MaxEPA), 209 (type IV), 224, 258, 263, 277, and 299).

Few studies have controlled for effects of PUFA's by giving a PUFA supplement. Two papers found no change in HDL in normal subjects fed fish oil as Promega (Ref. 73) or MaxEPA (Ref. 166) compared to wheat-germ oil or safflower oil (Refs. 73 and 166, respectively). Cobiac et al. (Ref. 20) reported increased HDL for mildly hypertensive subjects fed salmon and sardines in sild oil compared to those given a safflower-olive oil mix, but in comparable subjects, Meland et al. (Ref. 247) found no change in HDL cholesterol after MaxEPA fish oil compared to when the subjects were given a corn-olive oil mix. Very recent results, also for a mildly hypertensive population, found increased HDL after either, ethyl esters of EPA and DHA, or after corn oil (Ref. 177). Thus, for normal and hypertensive subjects, the change in HDL appears to not be a specific effect of omega-3 fatty acids, but may be related nonspecifically to increased PUFA's, either omega-3 fatty acids or omega-6 fatty acids.

In contrast, there are two reports of increased HDL cholesterol in subjects with type IIb hyperlipidemia fed fish oil compared to safflower oil (Ref. 166) or a corn-olive oil mix (Ref. 209), and one report of increased HDL in type IIa hyperlipidemics after fish oil or olive oil compared to corn oil (Ref. 286). Others found fish oil did not change HDL in type IV hyperlipidemics (Refs. 166 and 209) or patients with CHD (Ref. 258) compared to PUFA controls.

Therefore, at this time, FDA concludes that there is some evidence that omega-3 fatty acids, in some form and amount and in some selected populations, may increase HDL cholesterol, but that current data are ambiguous because the conditions under which fish oils reliably increase (total) HDL cholesterol have not been established, either in a specific subpopulation, or in the general population.

When fractions of HDL cholesterol have been reported, an increase has generally been found in the HDL_2 fraction (Refs. 1, 9, 54, 148, 191, 202, 203, 220, 235, 251, and 286), with a comparable decrease in the HDL_3 fraction (Refs. 202, 235, 251, and 286). Interestingly, the two recent reports that failed to find increased HDL_2 both used esterified omega-3 fatty acids rather than the fish oil triglyceride (Refs. 191 and 224), although others using ethyl esters have found increased HDL_2 (Refs. 9 and 286).

These studies suggest that fish oils produce a shift within the HDL fractions toward a lipid-rich, and away from a protein-rich lipoprotein, as well as within the LDL fractions. This shift may occur whether or not there is any change in total HDL cholesterol. FDA noted (56 FR 60663 at 60669) that some studies among normal subjects found increases in the HDL_2 fraction of HDL cholesterol, and that these reports were the most promising changes in blood lipids. New studies published after the period covered in FDA's review of the literature, however, found that both HDL_2, and HDL_3 were correlated with reduced risk of MI (Refs. 185a and 287a), and the NHLBI consensus conference (Ref. 255) concluded that, "The current studies of HDL_2 and HDL_3 levels have not shown consistent associations with CHD." Therefore, data on changes in HDL subfractions after increased consumption of omega-3 fatty acids do not provide a sufficient basis for a health claim, because there is not significant scientific agreement that the endpoints are directly related to risk of CHD. If the risk of CHD becomes linked with particular subfractions of these lipoproteins, these findings in normal subjects may be of great importance.

However, FDA also notes that recently published data from a prospective study demonstrate an effect of aspirin consumption in reducing the incidence of first heart attacks among women (Ref. 243). Another study shows a relationship between spontaneous platelet aggregation in vitro and incidence of CHD (Ref. 288). Both studies were conducted in the general population and their results support the hypothesis that platelet aggregation is a useful marker for CHD risk in the general population. Additionally, preliminary data from the Caerphilly Collaborative Heart Disease Study (Ref. 302) supports a relationship between platelet aggregation and the incidence of

ischemic heart disease; final data from this study will be available in the near future. These recently published and forthcoming studies may provide the basis for significant scientific agreement regarding the use of platelet function as a surrogate marker for CHD risk among the general population.

ii. Vessel wall effects.

New human studies on the effects of omega-3 fatty acids on vessel wall effects were discussed in response to comments 35 through 37 of this document. A recent meta-analysis of studies on use of fish oils in the prevention of restenosis concluded that the most plausible interpretation of the results was that there was a small to moderate beneficial effect of fish oils, but that chance could not be ruled out as a cause of the results (Ref. 260). The authors noted a significant heterogeneity in the findings and concluded that data from a large clinical study are necessary to confirm their interpretation. No study of restenosis to date has compared fish oil to an alternate polyunsaturated oil to control for nonspecific effects of PUFA's.

b. Thrombosis and hemostasis

i. Bleeding times

A number of studies have reported data that show no significant effect of fish oils on standardized bleeding time tests (Refs. 179, 218, 253, 268, and 277). However, others have found a significant increase in bleeding time due to fish oil (Refs. 195, 219, 220, and 278) or salmon (Ref. 297) or have reported increased bleeding as a side effect of treatment (Refs. 189 and 295).

ii. Platelet aggregation.

Consistent with the literature previously reviewed, recent studies show that fish oil tends to decrease platelet aggregation to numerous stimuli including AA (Refs. 179 and 256), adenosine diphosphate (ADP) (Refs. 204, 256, and 297), collagen (Refs. 218, 241, 251, and 297), thrombin (Ref. 241), and PAF (Ref. 251). Only one of these studies controlled for effects due to PUFA's (Ref. 204). The importance of the polyunsaturated fat control is less critical for studies on platelet function than for studies on blood lipids, because nonomega-3 PUFA's (i.e., omega-6 fatty acids derived from plant oils) produce effects in the opposite direction in platelets as omega-3 fatty acids (whereas many of the blood lipid effects of these two classes of fatty acids are in the same direction). Thus, the effects of omega-3 fatty acids on platelet responsiveness are not likely to be produced by PUFA's in general.

The only new study among healthy subjects that reported no difference in responsiveness to ADP used EPA ethyl esters as the source of omega-3 fatty acids (Ref. 179). Furthermore, the data were not shown in this brief report, so it is not clear if there was a trend toward an effect that might not have been statistically significant due to small number of subjects (eight per group). Those studies in healthy subjects reviewed in the proposed rule that did not find statistically significant differences in platelet responsiveness to ADP did have trends in the direction of reduced responsiveness (Refs. 24 and 54).

Other studies found no effect of fish oils on platelet aggregation in response to collagen (Refs. 179, 256 and 277). Each of these studies had a relatively small number of subjects, and there was a trend toward decreased sensitivity toward collagen at a high dose of omega-3 fatty acids in one study (Ref. 277). However, in the recent metabolic ward study (Ref. 256) there was no trend toward decreased sensitivity toward collagen or thrombin. These findings contrast with the results described above (Refs. 218, 241, 251, and 297) and with studies in healthy subjects described in the proposed rule (Refs. 2, 24, 54, 96, 143, and 166).

Studies reporting no effect of fish oils on PAF or AA-induced platelet aggregation (Refs. 179 and 218) may not have had sufficient power to find a statistically significant difference; where the data were reported there was a trend toward decreased sensitivity for both agents (Ref. 218).

iii. Platelet adhesion

A provocative study by Li and Steiner (Ref. 234) showed a 60-percent decrease in the extent to which platelets prepared from subjects fed fish oils adhered to substrates in a laminar flow chamber. The high flow rates used in this experiment showed that the change in adhesiveness of the platelets was due to changes on the platelet surface, and not due to a difference in the amount of material released from platelets that subsequently caused adhesion (i.e., AA). Also, a dose-response relationship was observed, and the time to return to pre-fish oil adhesion values was related to the amount consumed.

However, another study found no effect on fish oils on in vitro platelet adhesion to everted rabbit aorta, although there was a trend toward increased adhesion after 2 and 4 weeks of supplementation (Ref. 264). The reperfusion assay used in this study does not distinguish platelet membrane effects from effects mediated by substances released from platelets. Neither of these studies used a nonomega-3 PUFA control.

iv. Regulators of bleeding

Two recent studies in normal subjects have reported that omega-3 fatty acids have no effect on the clotting protein fibrinogen (Refs. 183 and 210), although in one of these studies a large supplement of vitamin E was associated with a decrease (Ref. 210). An uncontrolled study in normal subjects found a decrease in fibrinogen after fish oil supplementation (Ref. 278).

Studies on subjects at risk for CHD have reported no change (Ref. 203), a decrease (Refs. 276 and 277), and an increase in fibrinogen (Ref. 287). In agreement with its tentative conclusion in the proposed rule, FDA finds that the data on the effects of omega-3 fatty acids on fibrinogen level are ambiguous, because they do not distinguish effects due to PUFA's from effects specific to omega-3 fatty acids.

Plasminogen is an enzyme that dissolves clots. Plasminogen activator is a substance that increases clot dissolving; plasminogen activator is specifically inhibited by another substance, the PAI–1. Thus, a high level of PAI–1 decreases the capability to dissolve clots.

Three recent studies reported increased concentrations of PAI–1 after fish oil supplementation (Refs. 254, 278, and 287), which would appear inconsistent with a clot-dissolving effect of fish oil. Two of these investigators also found no change in the amount of plasminogen activator (t-PA) after supplemental fish oil (Refs. 254 and 287) including one who used a very specific immunologic assay (Ref. 254), suggesting that fish oils do not increase clot dissolution by increasing the amount of this protein. The third group, however, found an increase in the activity of tissue plasminogen activator (Ref. 277), which suggests that fish oils might increase clot dissolution by a different mechanism than affecting the amount of activator. Another group found no effect of cod liver oil on t-PA activity or fibrinolysis measured directly (Ref. 216). These reports are in contradiction to a report of increased fibrinolytic activity after a fish or fish plus fish oil diet (Ref. 183). FDA has not been able to find a reason for this rather marked contradiction. Therefore, in agreement with the conclusion in its proposed rule, FDA finds there is no clear relationship between omega-3 fatty acids and factors involved in dissolving blood clots, or clot dissolution activity.

Numerous investigators (Refs. 174, 191, 210, 220, 235, 241, and 279) have

recently reported that fish oils do not affect the concentration of Lp(a), a lipoprotein correlated with the risk of CHD. One investigator reported that very high levels of fish oils (9 g EPA plus DHA/day) gave a trend toward lower values, but the response may have been due to the PUFA's (Ref. 279). One study reported no effect overall of fish oils on Lp(a) among hypertriglyceridemics, but Lp(a) was reduced in those whose initial values were high (Ref. 174). On the basis of these reports and those reviewed in the proposed rule, FDA concludes that omega-3 fatty acids do not affect the risk of CHD by lowering Lp(a).

v. Blood pressure

Most of the studies not reviewed in the proposed rule that report data on blood pressure after consumption of fish oils have not found a significant change. One study of 50 elderly, healthy subjects reported that fish oils in combination with a salt-restricted diet decreased both systolic and diastolic blood pressure, but that fish oil alone had no effect (Ref. 190). There was a reduction in blood pressure during the run-in period, when the polyunsaturated fat placebo, sunflower oil, was fed.

Most studies on subjects with mild hypertension also have reported no change (Refs. 247, 277, and 289), including one large, randomized, placebo-controlled, multicenter trial of various behavioral changes and dietary supplements (Ref. 289). One study in hypertensives found reduced systolic and diastolic blood pressure comparable to reductions after the hypertension medication propranolol (Ref. 285), and in some cases the combined treatment of fish oil plus propranolol gave a greater decrease than either treatment alone. This study was controlled by olive oil (which is predominantly monounsaturated fatty acids), and therefore does not distinguish effects of omega-3 fatty acids from other PUFA's. Another double-blind randomized, placebo-controlled study in hypertensives whose blood pressures were maintained by medications found comparable blood pressure lowering compared to pretreatment values by fish oil or olive oil placebo (Ref. 299).

One uncontrolled study among hyperlipidemics also found reduced systolic and diastolic blood pressure (Ref. 263), but no effect was found in uncontrolled trials in subjects with end-stage renal disease (Ref. 207) or diabetics (Ref. 215). In a polyunsaturated fat (corn oil) controlled study on subjects with stable claudication (Ref. 203) fish oil and corn oil both reduced diastolic blood pressure comparably, but systolic blood pressure was only reduced by the corn oil treatment.

The results of these studies support the tentative conclusions reached in the proposed rule, that omega-3 fatty acids reduce blood pressure to a small degree in hypertensive people, but that it is not clear if there is any specific effect among normal subjects.

3. Other relevant information

a. Animal studies

Animal studies are especially important for studying effects of long-term consumption of omega-3 fatty acids, where there are few data from human intervention studies. The animal studies cited in the proposed rule related to the ability of omega-3 fatty acids to inhibit the development of atherosclerosis, an area not readily available for study in humans. A more complete discussion of the previously cited studies, with emphasis on those studies in nonhuman primates, is given in response to comment 47 of this document. Other recent animal studies cited in the comments or found during FDA's updated literature search that provide data on the development of atherosclerosis (where atherosclerosis is measured directly) are reviewed here. Also reviewed are studies on effects of omega-3 fatty acids during experimental ischemia, obviously not available for human study.

i. Atherosclerosis

One recent study in rabbits found less atherosclerosis in fish oil-supplemented animals, but there was no control for PUFA's, and the fish oil-treated animals also had reduced serum cholesterol (Ref. 192). Because humans do not have reduced serum cholesterol after fish oil consumption, these results are of questionable relevance to humans. Furthermore, the effect cannot be attributed specifically to omega-3 fatty acids rather than to polyunsaturated fats in general.

Fish oil feeding has also been associated with reduced binding of LDL to the blood vessel endothelium in monkeys (Ref. 193), and purified EPA ethyl ester was reported to reduce susceptibility of LDL to oxidation (Ref. 273), but these studies did not control for PUFA's. The antioxidant levels in the diets with respect to the amount of omega-3 fatty acids may be as important in determining whether or not there is any effect of omega-3 fatty acids on the oxidation of LDL.

Three recent papers describe effects of fish oils fed before surgical grafting of a vein into an artery, a procedure associated with an accelerated development of atherosclerosis. Two papers (Refs. 275 and 303) each used a polyunsaturated fat control and studied fish oil effects after vein allografts in animals treated with the immunosuppressant cyclosporin. In one study (Ref. 303), six groups of rabbits received one of three amounts of fish oil (giving 29, 87 and 174 mg EPA plus DHA/kg, respectively, similar amounts to those used in most human studies) or comparable amounts of safflower oil. In this study, safflower oil was more effective at reducing cholesterol than fish oil, and there was a trend toward more protection from atherosclerosis in the safflower oil-fed group. In the other study (Ref. 275), rats received, in addition to cyclosporin, either fish oil (containing 210 mg EPA plus DHA/kg), or safflower oil with aspirin, or safflower oil only. The fish oil group had remarkably less atherosclerosis than the other two groups. The contradictory results in these two studies, both of which used the same model of vein allografts with cyclosporin immunosuppression and the same polyunsaturated fat control, may be related to dose and species differences.

A third study of vein allografts in dogs (Ref. 274) found significantly less atherosclerosis in fish oil-fed animals either fed the fish oil alone or in combination with aspirin or a thromboxane synthetase inhibitor. Other animals were treated with aspirin only or a thromboxane synthetase inhibitor only. There was no difference among groups for blood lipids, platelet function or eicosanoid metabolism. This study suggests that mechanisms of atherosclerosis other than those involving blood lipids and platelet function may be affected by omega-3 fatty acids.

These animal models are most relevant to comparable surgical procedures or other invasive procedures (e.g., angioplasty) that would be expected to activate platelets in humans. Use of omega-3 fatty acids in these settings is a drug usage, but provides information on the extent to which omega-3 fatty acids may modify platelet response in vivo. The very different results of omega-3 fatty acids in modifying the response to vein allografts in immune-suppressed animals indicates that the actions of omega-3 fatty acids in these settings are not yet well established.

ii. Response to ischemia

One major line of research on omega-3 fatty acids in animals is experimental ischemia (deficiency of blood flow to

the heart). Force et al. (Ref. 199) found that rats fed a diet containing a high amount of fish oil (20 percent of the diet) for 6 to 12 weeks had much greater blood flow once the occlusion was removed than rats fed diets enriched in corn oil or lard. There were no differences among diet groups in the amount of tissue damaged by ischemia. Increased blood flow after ischemia has also been reported in a pig model (Ref. 221). This study did not control for polyunsaturated fat and used a lower amount of omega-3 fatty acids, and the differences in blood flow were not as pronounced as in the Force study. Another study found evidence of less tissue damage during reperfusion when rats had been fed a diet with 12 percent fish oil compared to other rats fed the same level of corn oil (Ref. 223). Another study in yet a third animal species (Ref. 230) showed that the functional capillary density was preserved during reperfusion in hamsters fed 5 percent fish oil for 4 weeks prior to experimental ischemia.

A reperfusion study in dogs determined the effects of fish oil on the duration of time needed for drug-induced reperfusion following an electrically induced blockage, and on the occurrence of spontaneous reocclusion in the reopened vessel (Ref. 182). High amounts of fish oil (one-third of total calories) for 3 weeks before the surgery resulted in a shorter time needed for the drug-induced reperfusion, but did not affect the time necessary for the electrically mediated occlusion to occur, the occurrence of second occlusion, or the time it took for the second occlusions to appear. This study did not have a polyunsaturated fat control, and even at the high intake only a modest effect of omega-3 fatty acids on platelet function was seen, that being primarily an enhancement of the effects of the fibrinolytic drug.

Another possible consequence of ischemia is arrhythmia, when the heart fails to maintain its normal rhythmic beating. The effects of fish oils on arrhythmia in monkeys are discussed in response to comment 39 of this document. Similarly, data have been reported for experimental ischemia in rats that show that both fish oil and sunflower oil reduced the occurrence of arrhythmia during occlusion and reperfusion compared to a saturated fat diet (Ref. 246). Another study, done on isolated, cultured rat heart cells (myocytes) showed that EPA, but not AA, prevented a known toxin (ouabain) from disturbing the rhythmic contractions and killing the cells (Ref. 212). The effective amount of EPA was so low that the mode of action was proposed to be due to production of an active metabolite, rather than due to direct effects of EPA on the cell membranes. This study suggests a specific effect of EPA in stabilizing the heart myocytes during stress. Prevention of arrhythmia by stabilization of these heart cells has been proposed as a mechanism by which omega-3 fatty acids may increase the chances of survival following a heart attack as reported in the Dart study (Ref. 16).

These studies indicate that, in various animal models, dietary fish oils promote greater reestablishment of blood flow in heart tissues following a transient block, as occurs in an acute heart attack. Importantly, the results are consistent across many animal species, and in some cases have been shown to be specific for omega-3 fatty acids rather than simply due to any PUFA. Finally, the experimental designs included coronary occlusions in otherwise healthy animals who were not suffering from heart disease, a model relevant for use of omega-3 fatty acids in reducing the risk of CHD rather than in therapy for persons with preexisting heart disease. The studies remain limited in that ischemia was produced by an acute blockage produced by mechanical or electrical means rather than by chronic dietary means, and the response to these different types of block may not be the same.

Other studies have attempted to learn the mechanism by which the platelet-vessel wall interactions are modified by omega-3 fatty acids. One study (Ref. 240) found that aortas from rats fed fish oil or corn oil did not contract as much in response to agents that cause contraction as aortas from rats fed beef tallow (saturated fat). This was true both before and after oxygen deprivation. The aortas from fish oil-fed rats were more responsive to one of three tested chemical relaxers than aortas from corn oil-fed or beef tallow-fed rats. Another study found that EPA potentiated the release of an EDRF (Ref. 181), but the effect was thought to be related to the unsaturation of the EPA, because the experiments were carried out in the presence of inhibitors of EPA metabolism.

One research group has recently shown that leukotrienes, chemicals produced from AA, are important in the tissue injury that accompanies reperfusion (Refs. 230 and 232). Since EPA competes with AA for the enzyme that makes leukotrienes from AA, EPA could potentially reduce the amount of leukotriene formed from AA. This same group has shown that leukotrienes promote the adhesion of leukocytes to the vessel wall (Ref. 231), and that feeding hamsters fish oil at 5 percent of the diet for 4 weeks greatly reduced (over 60 percent) the adhesion of leukocytes to the vessel wall (Ref. 233). The reduced adhesion could be relevant for both the conditions during which atherosclerosis develops (indeed, the stimulus used to elicit leukocyte adhesion was oxidized LDL, a candidate for promoting atherosclerosis in humans), and the acute response to coronary ischemia.

These animal data suggest mechanisms by which omega-3 fatty acids could affect the development of atherosclerosis or the response of heart tissue after a transient occlusion of its blood flow. Both modes of action could make important contributions to the risk of CHD and, therefore, merit additional study. The reperfusion studies and the myocyte toxicity study have demonstrated specificity of the effect as to omega-3 fatty acids. However, the increase in reperfusion volume is not sufficient to ensure a reduced risk of CHD death. Omega-3 fatty acids may not affect the extent of tissue damaged during an occlusion, or the tendency for a second, spontaneous occlusion. Additionally, omega-3 fatty acids may not affect tissue vulnerability during reperfusion. Those studies where CHD deaths or second occlusions have been recorded used large amounts of fish oils, and do not indicate whether amounts of omega-3 fatty acids found in the diet would have the same effects. Thus, there are many possible avenues suggested by these animal studies for beneficial effects of omega-3 fatty acids on the development of CHD, but there are also important limitations in the study designs and models used that prevent drawing conclusions from these data about the importance of omega-3 fatty acids in reducing the risk of human CHD.

b. Safety concerns

i. Diabetes

Three additional papers (Refs. 170, 222, and 304) and one major review (Ref. 238) on the effects of fish oils in diabetics were published after the time period reviewed in the proposal. All three new studies found increased LDL cholesterol after fish oil consumption in type II diabetics. However, effects on fasting glucose varied, with no change (Ref. 170), a transient increase (Ref. 222) or an increase (Ref. 304) reported. Although fasting insulin concentration was unchanged after fish oil (Refs. 170 and 304), postprandial insulin response usually, but not always (Ref. 170), has been reported as reduced (Refs. 238 and 304).

These effects of fish oils on blood glucose appear to depend on the amount of fish oils fed. One study found no change in fasting blood glucose levels among type II diabetics treated with 3.0 g/day EPA plus DHA for 2 weeks (Ref. 170). Two other studies that used 3 or 2.7 g/day EPA plus DHA for 6 and 8 weeks (Refs. 222 and 79) only found transient increases in blood glucose halfway through their respective supplementation periods. A fifth study (Ref. 12) that used 3.0 g/day EPA plus DHA for 3 weeks found comparable increases in fasting blood glucose when either fish oil or safflower oil was fed, so the increase cannot be attributed specifically to the omega-3 fatty acids. Similarly, Vessby and Boberg (Ref. 157) fed 3 g/day EPA plus DHA and did not find a difference in fasting glucose or glycosylated hemoglobin after fish oil supplementation compared to baseline; they did find a significant difference compared to the olive oil treatment that produced changes in the opposite direction from fish oil. Studies on type II diabetics that reported increased glucose used higher amounts (4.5 to 8 g/day) of omega-3 fatty acids (Refs. 52, 55, 128, and 304). Thus, FDA concludes that glycemic control among diabetics remains a valid safety concern, but notes that restriction of the amount of supplemental omega-3 fatty acids may suitably address this concern.

ii. Increase in LDL cholesterol

Many studies published after 1987 with data for LDL or apoB report increased LDL cholesterol or apoB after fish oils, in hypercholesterolemic or hypertriglyceridemic subjects (Refs. 1, 26, 32, 55, 60, 61, 63, 73, 75, 94, 114, 119, 120, 129, 146, and 166). Virtually all the studies with 10 or more subjects supplemented with 5 g/day EPA plus DHA or more found increased LDL. Some studies on normal subjects (all of which were reviewed in the proposed rule) also report increased LDL or apoB after fish oil consumption (Refs. 54, 127, and 156). Many studies that found no effect may not have had sufficient sample size to detect a difference due to treatment. FDA concludes that increased LDL cholesterol among some populations already at increased risk of CHD remains a valid safety concern, but because most reports of increased LDL are in studies where large amounts of fish oils are given, it is possible that restriction of the amount of supplemental omega-3 fatty acids and/or changes in the fatty acid composition of omega-3 fatty acid supplements may suitably address this concern.

III. Overall Summary and Conclusions

FDA concludes that there is some evidence that supports a relationship between omega-3 fatty acids and CHD, but that the totality of scientific evidence available at this time does not provide an adequate basis for a health claim. In some cases, there is not significant scientific agreement that the changes that are specific to omega-3 fatty acids will reduce the risk of CHD. In other cases, the data do not demonstrate that the effect is specifically due to the omega-3 fatty acids and not due to other dietary variables. For yet other cases, the data are ambiguous because effects of omega-3 fatty acids are not consistently observed, which suggests that other variables are important in determining whether or not an effect is seen. Therefore, the agency does not consider the evidence sufficiently strong to draw a firm conclusion about the relationship between omega-3 fatty acids and risk of CHD, and therefore is not authorizing the claim at this time.

In the course of developing this regulation, FDA has identified some areas where greater agreement is needed that the effects produced by omega-3 fatty acids are directly related to the risk of CHD. Many surrogate markers have been hypothesized, on the basis of limited evidence, to be related to specific diseases, including CHD, but few have withstood the continued scrutiny of scientific investigation. Also, some markers may have scientific validity, but may not be applicable for use in the general population, because of technical limitations. Thus, FDA asserts that only when a surrogate marker for a disease has been accepted as a risk factor for the general population, as indicated by a statement by an unbiased, nationally representative authoritative scientific or medical body, can the agency authorize a health claim based on the relationship of a nutrient to the surrogate marker of the disease. Examples of potential surrogate measures for which validation is needed are in vitro platelet aggregation, in vitro platelet adhesion, elevated fasting triglycerides postprandial triglycerides (recently considered at the NHLBI consensus development conference, Ref. 255), and subfractions of LDL and/or HDL.

In some cases additional research is needed to determine whether hypothesized subpopulations, e.g., those with high LDL:HDL ratio and high triglycerides, are at increased risk of disease. The pronounced triglyceride lowering effects of omega-3 fatty acids might well have a protective effect against CHD in such a subpopulation.

There are other areas where additional research is needed to show, for agreed endpoints, that the effects are consistently produced, or are specifically due to omega-3 fatty acids. These areas require additional data to establish that the effect of omega-3 fatty acids is specific, or to further define the conditions under which omega-3 fatty acids have their effects. For example, data are needed to show a reduction in MI or CHD mortality among individuals fed supplemental omega-3 fatty acids (specifically) compared to a group fed omega-6 PUFA's. The critical failing of some recent studies associating omega-3 fatty acids and CHD is that specificity was not obtained. Future studies should carefully control for known confounders, particularly dietary variables.

Finally, the available data suggest that some set of conditions or population may exist for which omega-3 fatty acids will increase HDL. Additional research should be able to define the conditions under which omega-3 fatty acids have this effect.

Interested parties may choose to petition the agency for approval of other health claims about omega-3 fatty acids. For example, additional data may be developed to support an omega-3 fatty acids/hypertension health claim petition. Because the blood pressure-lowering effect of omega-3 fatty acids appears most marked against a background of very low dietary intakes of omega-3 fatty acids, the role of omega-3 fatty acids in the total diet would need clarification before such a petition could be adequately supported. Similarly, limitations of the effects of omega-3 fatty acids on the magnitude and duration of change in blood pressure, the quantitative amounts of omega-3 fatty acids required for the effects, and characterization of the sensitive subpopulation would require discussion in a petition. A petition should also address apparent conflicting pieces of information, e.g., high blood pressure among populations that have high intakes of omega-3 fatty acids. Safety concerns raised in this final rule will, of course, require resolution prior to the authorization of any petitioned claim.

IV. Decision Not to Authorize a Health Claim Relating Ingestion of Omega-3 Fatty Acids to Reduced Risk of CHD

In evaluating the scientific evidence, FDA considered: (1) The strength of the association of omega-3 fatty acids with CHD or surrogate markers for CHD, (2) the consistency of findings among the

many studies, (3) the specificity of the outcome to omega-3 fatty acids, (4) the presence or absence of a dose-response relationship, and (5) the biologic plausibility of an association. FDA has determined that there is inadequate evidence to show that increased consumption of omega-3 fatty acids will reduce the risk of CHD.

FDA sought to determine whether there was significant scientific agreement among qualified experts that the totality of publicly available scientific evidence supported the claim that omega-3 fatty acids reduce the risk of heart disease. FDA reviewed the position taken in numerous Federal Government reports and other authoritative scientific reports and evaluated the publicly available scientific evidence that has become available since those reports were written. The decision to deny a health claim is based on the conclusions reached following review of the following sources of information: (1) "The Surgeon General's Report on Nutrition and Health;" (2) the National Research Council's "Diet and Health: Implications for Reducing Chronic Disease Risk," and (3) the National Cholesterol Education Program's Report of the Expert Panel on Detection, Evaluation and Treatment of High Blood Cholesterol in Adults. Each of these reports concluded that there was inadequate evidence of a relationship between consumption of omega-3 fatty acids and CHD. FDA has reviewed again all of the relevant cross-sectional data from which the hypothesized relationship between omega-3 fatty acids and CHD originated, and all clinical intervention data published since these Federal Government and other authoritative reports were issued to determine whether the additional evidence is adequate to support a health claim for omega-3 fatty acids.

The LSRO report reached a different conclusion from the other authoritative reports by finding a relationship between omega-3 fatty acids and CHD. The report used only selected evidence, and often did not distinguish effects specifically due to omega-3 fatty acids from effects due to PUFA's in general. The description of international epidemiologic findings of a relationship between fish consumption and CHD, similarly, was not shown to be specific to omega-3 fatty acids. In some instances, FDA disagreed with the interpretation of the studies reviewed by LSRO, or with LSRO's conclusions. Finally, the LSRO report also based its conclusions about the usefulness of omega-3 fatty acids, in part, on changes in blood lipid parameters that are not generally agreed to be risk factors for CHD. Therefore, FDA finds numerous reasons for not accepting all of the findings of the LSRO report. FDA's conclusions regarding the relationship between omega-3 fatty acids and CHD rely instead on FDA's independent review of the publicly available scientific information, and are consistent with the Federal Government and other comprehensive and authoritative reports except for the LSRO report.

The surveys, cross-sectional studies, and nonintervention prospective studies do not provide adequate support for a relationship between consumption of omega-3 fatty acids and CHD. Only a few studies found an association between fish intake and CHD, while others have found no association; thus, there was no consistency of findings. None of the studies that reported a relationship distinguished fish consumption from other factors associated with fish consumption, and therefore none demonstrates specificity. Even in those studies that reported a relationship between fish consumption and CHD, it is not clear that the observed effects were due to the omega-3 fatty acids in fish. Also, the omega-3 fatty acid content of the fish diet associated with reduced CHD in these studies was so low that the importance of omega-3 fatty acids is questionable, thus weakening the biologic plausibility of the relationship.

The data from intervention studies also do not establish a relationship between omega-3 fatty acids and risk of CHD. The most compelling type of evidence to support a diet-disease relationship is a prospective, double-blind, placebo-controlled intervention study, with CHD morbidity and mortality as endpoints. To date, there is only one such trial (Ref. 16). The results of that study showed that increased consumption of fish does not reduce the risk of a second heart attack but may reduce the risk that the attack will be fatal. This study provides evidence for a protective effect of fish consumption against second heart attacks. However, as with the nonintervention study data, this study did not provide evidence to attribute the benefit to omega-3 fatty acid intake rather than some other factor associated with fish consumption (specificity).

Less persuasive than prospective studies in which CHD per se is measured, but still very useful, are prospective clinical trials in which surrogate markers for CHD are measured. Recent studies have not found beneficial effects from omega-3 fatty acids on total cholesterol or LDL cholesterol in normal, healthy persons, or among persons at risk for CHD. Numerous studies, including some large or multicenter studies, have reported these results, demonstrating consistency in the findings and providing the agency confidence that they were not spurious. The data on HDL cholesterol are ambiguous. There appear to be other factors in the dietary interventions besides the omega-3 fatty acids that determine whether or not supplementation with fish or fish oils raises HDL.

An increase in bleeding times and a decrease in platelet aggregation have been observed frequently, but not always, after supplemental omega-3 fatty acids in normal healthy individuals as well as in diseased persons. Additionally, there is evidence that platelet adhesion is reduced by omega-3 fatty acids. The effects of decreased platelet aggregation and platelet adhesion appear to be related to the intake of omega-3 fatty acids in a dose-response relationship. What has not been established, however, is that in vitro platelet aggregation or platelet adhesion are bona fide surrogate risk factors for CHD in the general population.

Omega-3 fatty acids have been shown to reduce blood pressure in hypertensive people to a small degree, which may bear on a relationship between omega-3 fatty acids and CHD. This effect was not of large magnitude, but it is specific to omega-3 fatty acids, it has been reported by a number of investigators, a dose response was found, and the effect is biologically plausible through at least two mechanisms. However, it has not been established that omega-3 fatty acids reduce blood pressure in normal subjects (lack of consistency, weak effect, absence of dose-response relationship). Additionally, it has not been demonstrated that the magnitude and duration of changes in blood pressure observed in short-term studies will persist during long-term consumption of omega-3 fatty acids, or that these changes result in a reduced risk of CHD.

Finally, the potential that omega-3 fatty acids may increase LDL cholesterol and/or apoB among diabetics and hyperlipidemics, and the potential that omega-3 fatty acids may worsen control of blood glucose in diabetics are significant safety concerns that must be addressed before a claim may be made that consumption of omega-3 fatty acids by the general population will reduce the risk of CHD.

In conclusion, there are numerous effects of omega-3 fatty acids that may

be related to the risk of CHD, e.g., reduction in fasting and postprandial triglycerides, reductions in platelet aggregation and adhesion, changes in the composition of lipoproteins. However, at this time these endpoints are not generally agreed to be closely related to the risk of CHD. In other areas, additional data are needed to show that effects related to fish consumption are specifically due to the omega-3 fatty acids in the fish, and to define the conditions under which omega-3 fatty acids consistently increase HDL. These avenues may provide a reasonable basis for a future petition for a health claim relating omega-3 fatty acids to the risk of CHD.

V. Environmental Impact

The agency has determined under 21 CFR 25.24(a)(11) that this action is of a type that does not individually or cumulatively have a significant effect on the human environment. Therefore, neither an environmental assessment nor an environmental impact statement is required.

VI. Economic Impact

In its food labeling proposals of November 27, 1991 (56 FR 60366 et seq.), FDA stated that the food labeling reform initiative, taken as a whole, would have associated costs in excess of the $100 million threshold that defines a major rule. Thus, in accordance with Executive Order 12291 and the Regulatory Flexibility Act (Pub. L. 96–354), FDA developed one comprehensive regulatory impact analysis (RIA) that presented the costs and benefits of all of the food labeling provisions taken together. That RIA was published in the **Federal Register** of November 27, 1991 (56 FR 60856), and along with the food labeling proposals, the agency requested comments on the RIA.

FDA has evaluated more than 300 comments that it received in response to the November 1991 RIA. FDA's discussion of these comments is contained in the agency's final RIA published elsewhere in this issue of the **Federal Register**. In addition, FDA will prepare a final regulatory flexibility analysis (RFA) subsequent to the publication of the food labeling final rules. The final RFA will be placed on file with the Dockets Management Branch (HFA–305), Food and Drug Administration, rm. 1–23, 12420 Parklawn Dr., Rockville, MD 20857, and a notice will be published in the **Federal Register** announcing its availability.

In the final RIA, FDA has concluded, based on its review of available data and comments, that the overall food labeling reform initiative constitutes a major rule as defined by Executive Order 12291. Further, the agency has concluded that although the costs of complying with the new food labeling requirements are substantial, such costs are outweighed by the public health benefits that will be realized through the use of improved nutrition information provided by food labeling.

List of Subjects in 21 CFR Part 101

Food labeling, Reporting and recordkeeping requirements.

Therefore, under the Federal Food, Drug, and Cosmetic Act and under authority delegated to the Commissioner of Food and Drugs, 21 CFR part 101 is amended as follows:

PART 101—FOOD LABELING

1. The authority citation for 21 CFR part 101 continues to read as follows:

Authority: Secs. 4, 5, 6 of the Fair Packaging and Labeling Act (15 U.S.C. 1453, 1454, 1455); secs. 201, 301, 402, 403, 409, 701 of the Federal Food, Drug, and Cosmetic Act (21 U.S.C. 321, 331, 342, 343, 348, 371).

2. Section 101.71 is amended by adding new paragraph (f) to read as follows:

§ 101.71 Health claims: claims not authorized.

* * * * *

(f) Omega-3 fatty acids and coronary heart disease.

Dated: October 30, 1992.

David A. Kessler,

Commissioner of Food and Drugs.

Louis W. Sullivan,

Secretary of Health and Human Services.

Note: The following tables will not appear in the annual Code of Federal Regulations.

BILLING CODE 4160-01-F

Study	Study Design	Subjects	
Beswick et al. (Ref. 167).	Dietary counseling compared with survey data and platelet activity 6 months later. Men from Cardiff, Wales with history of myocardial infarction.	56 men, ages 36 to 71 (mean=58). 13 excluded for medication, 1 for inadequate blood sample. 18 smokers, 34 patients on cardiovascular medication, 19 on B blockers, 8 on antihypertensive drugs, and 24 on angina medication.	Question estimate polyunsa saturate percent fat, and Platelet on ADP a aggregat platelet plasma.
Bulliyya et al. (Ref. 185).	Dietary and serologic survey in Nellore and Chittor districts of India.	100 individuals in fish consuming populations and 109 individuals in nonfish consuming populations.	Dietary serum an cholest phospho Clotting times ob weight, blood pr tabulate
Bjerregaard and Dyerberg, (Ref. 176).	Analysis of CHD mortality rates, Greenland.	All deaths due to CHD in Greenland from 1968 to 1983.	A regist cause wa using in death ce parish r civil re records. was comp brought manageme Danish B from 197

TABLE 1

les: Omega 3 Fatty Acids and CHD

Methods	Results	Comments
tionnaire to mate unsaturated to rated fat ratio, snt calories from and EPA intake. slet activity based DP added for sgation of slets in blood and ma.	Significant inverse correlation between fat ratio and platelet activity. Nonsignificant trend for decreased platelet aggregation with increased EPA intake.	Study inconclusive on role of EPA in platelet activity. Small sample. In vitro assay not repeated for accuracy. Nutrient intake estimated. Health behaviors, medications, and other factors which may have influenced results not presented. Study population ill.
ary survey. Total m and HDL-esterol, TG, and pholipid measured. ting and bleeding s observed. Age, ht, pulse rate, d pressure lated.	Total serum cholesterol was lower in the coastal village (152.7 mg/dL) than in the nonfish consuming village (214.9 mg/dL). HDL-cholesterol was higher in the coastal village.	Dietary survey methods not presented in paper. Dietary intake was presented as correlational data. The potential confounding effect of other components of diet on cholesterol level warrants explanation. Lower total cholesterol level in the fish eating population was observed.
gister of deaths by e was developed g information from h certificates, sh registers, and l registration rds. The register computerized and ght under the gement of the sh Board of Health 1975 to 1983.	Age standardized mortality rates per 10,000 person-years for CHD in men in Greenland settlements (5.3) were half those of men in Denmark (10.0). There was an increasing rate of CHD from settlements to towns in Greenland. The difference in rates of CHD in women were less apparent, with lower rates in Denmark than in towns in Greenland.	Genetic protection, exercise and confounding factors such as tobacco use cannot be eliminated as factors in this observation. These data support earlier observations of lower CHD rates in male Greenlanders versus Danes, but not for females. Note, the 50 percent difference is approximately the same as reported by Kromhout for comparing men eating no fish and those eating approximately 30 g/day.

Van Houwelingen et al. (Ref. 293).	Sample of clinical parameters from 61 elderly male volunteers from longitudinal cohort. Zutphen, Holland.	61 healthy elderly male volunteers ages 67 to 82. Lowest quartile of fish consumption ate 0 g/day. Highest quartile ate 27 g/day.	Cross-chec history wa assess the intake of polyunsatu acids. Blo collected controlled for measur serum tota phospholip and chole

LE 1--CONTINUED

Methods	Results	Comments
-check dietary ry was taken to s the habitual e of nsaturated fatty . Blood was cted under rolled conditions easurement of total lipids, pholipids, TG's, cholesterol esters.	Dietary history seemed to correlate with serum linoleic acid. The correlation between dietary history using the cross check method for fish consumption and serum level of fish-related fatty acids, however, seems less reliable.	The discrepancy between dietary history and serum level of fish-related fatty acid may be the result of large variation in the level of these fatty acids in the same foods.

TABLE 2

Intervention Trials of Omega-

Study	Study Design	Subjects	Methods
Agren et al. (Ref. 168).	Randomized parallel trial of fish, fish plus reduced fat (especially saturated fat) or usual diet (one fish meal per 2 weeks) for 15 weeks.	62 Normal, healthy female students.	Plasma lipids and lipoproteins at baseline, 7 and 1 weeks.
Annuzzi et al. (Ref. 170).	Randomized double-blind crossover trial of 10 g fish oil/day (3.0 g EPA plus DHA, MaxEPA) versus olive, no wash out, 2 weeks each treatment.	Eight female NIDDM, without liver, kidney or any other disease known to influence lipid and/or carbohydrate metabolism.	One of the patien treated by diet o others on Glibenc (4) and metformin The patients were dietary control a were in the metab ward.
Bairati et al. (Ref. 172).	Randomized, double-blind placebo-controlled trial of 15 g fish oil/day (MaxEPA, 4.5 g EPA plus DHA) versus olive oil from 3 weeks pre angioplasty to 6 months; concurrent aspirin.	119 Subjects undergoing first, successful, computer quantified percutaneous transluminal coronary angioplasty, evaluated also at 6 months.	Angiographic asse quantified by com diet by food freq Restenosis define four ways for ana

ods	Results	Comments
and at nd 15	Controls: NS TG, cholesterol, $apoA_1$, apoB. Fish eaters: NS versus baseline TG, cholesterol, apoB; ↓ $apoA_1$; ↓ TG versus controls. Fish plus low fat: ↓ TG, cholesterol, $apoA_1$, apoB.	This study shows the importance of the balance of the diet, particularly regarding saturated fat, in determining the blood lipid response to omega-3 fatty acids. Changes were slight unless a low fat low saturated fat diet was used. Study would have been stronger with a control group eating a low fat low saturated fat diet matched with fish intake to the nonfish control.
atients was iet only; lbenclamide ormin (3). were under rol and they etabolic	↓ TG, VLDL; ↑ LDL; NS cholesterol, HDL FFA; NS LDL-TG, HDL-TG; NS fasting glucose, average glucose insulin response, sensitivity.	Duration period was very short and no fatty acid analysis on neither fish oil nor olive oil diet. There was no washout period between cross-over of the study.
assessment, y computer. frequency. efined in r analysis.	By three of four definitions of restenosis, and multivariate analysis to control for exclusions, fish oil reduced restenosis. NS ECG evidence of myocardial ischemia, but trend toward ↓ fish oil, also on exercise testing. Significant difference also according to dietary omega-3 fatty acids (highest, middle versus lowest tertile) although highest tertile intake was only 0.15 g/day, and dietary odds ratio comparable to fish oil odds ratio.	Comparable compliance. Olive oil control doesn't control for polyunsaturated fatty acids. The comparable magnitude of the effects of dietary omega-3 fatty acids and fish oil supplementation suggest long-term, low dose effects are as strong as short-term, larger amounts. No associations of restenosis with other dietary variables, total fat, classes of fat, cholesterol, or dietary seafood. Differences between groups use of blood pressure medications (see Bairati et al. Ref. 173)) was not discussed.

Bhathena et al. (Ref. 175).	Nonblinded, longitudinal design, 10 week run-in on placebo (15 g mixed fat); 10 weeks with 15 g fish oil (anchovy oil, 6.5 g EPA plus DHA); 8 weeks of 15 fish oil plus 200 mg vitamin E	40 healthy females, no history of metabolic disease, no medication, no smoking.	Diet for th test group controlled, eliminated menu. Fort energy com dietary fa more than current di guideline

ABLE 2--CONTINUED

Methods	Results	Comments
ent blood re, blood lipids mercial kits.	Blood pressure increased in the olive oil control group, and was unchanged in the fish oil group, possibly because greater number of patients in the olive oil group discontinued concurrent blood pressure medications. Fish oil ↓ TG's, NS in cholesterol, LDL or HDL versus control, but the change from baseline was different between groups with ↑ LDL and HDL in fish oil.	Multiple linear regression analysis used to control use of blood pressure medications reduced differences in LDL and HDL to borderline significance (p = 0.06), and inclusion of TG resulted in NS change in HDL.
by standard s, Lp(a) by cial kit.	↓ TG in high fish oil group versus placebo; NS cholesterol, LDL, HDL apoB; NS Lp(a), post-hoc analysis shows ↓ Lp(a) in those initially greater than 10 mg/dL.	Although randomized, there were large differences in initial Lp(a) levels, with only 1 of 10 in the placebo group over 6 mg/dL versus 6 and 8 of 10 in the low and high fish oil groups, respectively. Therefore, on the basis of Lp(a) the randomization was inadequate. Oleic acid does not control for polyunsaturated fatty acids.
or the placebo and roup was lled, fish was ated from the Forty percent of comes from y fat which was han the level of t dietary ine recommended.	Fish oil ↑ fasting glucose; ↓ TG, insulin, glucagon, GH, somatomedin-C; NS cholesterol, cortisol, dihydroepiandrosterone sulphate. Fish oil plus vitamin E gave no further change in glucose, TG, glucagon cortisol or cholesterol; but ↓ GH, insulin, increased somatomedin-C to placebo levels, and produced a ↓ in DHEA-S.	Unusual source and high level of omega-3 fatty acids. Study design doesn't allow conclusions about omega-3 fatty acid-specific effects.

n, fish was pink tuna, herring, , pilchard. sumption in daily diary.	↓ TG's in both fish and fish oil groups; NS cholesterol, HDL; decrease in TG correlated with increase in EPA.	Baseline blood lipid values were comparable in the self selected groups.
a stable dilution method d in the laboratories.	Fish oil alone and fish oil supplemented with vitamin E produced comparable results on average, with the mean values µg PGE-M excreted per 24 hours in control, fish oil and fish oil plus vitamin E of 15.41 ± 2.12, 12.51 ± 1.78 and 12.77 ± 1.85, respectively. Paired t-test showed a significant ($p < 0.002$) reduction between baseline and fish oil treatment.	PGE-M is the sum of PGE_1 plus PGE_2, derived from AA. The EPA-derived PGE_3 was not measured. Dietary intake was well controlled. Prolonged use of fish oil supplementation was not recommended. The range of baseline values was from 3.8 to 60.9 µg/24 hours. There was no apparent relationship between initial values and magnitude of the change, and there were many individuals who had substantial differences for the two fish oil treatments. Thus, the significance of an average change of about 20 percent is not clear.
matography-mass copy	Fish oil ↓ TXA_2 38 percent, with ASA ↓ 97 percent at each dose; fish oil and ASA each ↓ PGI_2 (ASA more than fish oil); fish oil ↑ PGI_3, but ASA did not increase PGI_3.	This is a study on the mechanism of action of fish oil. No concurrent placebo control. Dietary intake was not controlled.

Study	Study Design	Subjects	Methods
Meland et al (Ref. 247).	Double-blind, randomized multi-center placebo (corn oil- olive oil mix) controlled trial, 20 mL MaxEPA/day (6.8 g EPA plus DHA), 6 weeks.	40 females mild hypertension.	Calibrated instruments at 8 centers. Time of day for measurements was controlled.
Meydani et al (Ref. 248).	Uncontrolled supplementation study 2.4 g/day EPA plus DHA (Promega), 3 months.	25 males.	Blood at 1, 2, 3 months.
Molvig et al. (Ref. 250).	Randomized, double-blind Placebo-controlled trial of 1.6, 3.2 g EPA plus DHA (Pikasol) versus fatty acid blend, 7 weeks.	25 Healthy subjects and 8 IDDM subjects.	Isolated monocyte cell cultures. TNF and IL-1 by commercial ELISA kits.
Mori et al. (Ref. 251).	Matched (age, weight) and randomized to 15 g MaxEPA/day (4.5 g EPA plus DHA) or olive oil, 4 weeks.	32 females with peripheral vascular disease.	No aspirin for 14 days prestudy platelet aggregation to PAF, collagen.
Mori et al. (Ref. 252).	Matched groups randomly assigned to 15 g/day MaxEPA (4.5 g EPA plus DHA), olive oil, or olive oil plus cholesterol.	27 normolipidemic insulin-dependent female diabetics.	HDL by heparin, manganese chloride precipitation, followed by separate precipitation of subfractions. LDL by calculation.

UED

	Results	Comments
nts of s was	NS blood pressure, cholesterol; ↓ TG's on fish oil; ↓ cholesterol/HDL ratio in both groups.	Power to detect a 5 mm blood pressure difference was 96 percent; a 10 percent cholesterol difference was 61 percent. Cholesterol/HDL ratio decrease in placebo was nearly more than that after fish oil ($p<0.07$). 11 of 14 subjects on fish oil guessed their assignment correctly.
nths.	↓ TG's; ↑ lipid peroxides.	6 IU vitamin E may not be adequate.
ell IL-1	↓ IL-1B immunoreactivity on high dose only; NS after low dose. NS TNF-α; ↓ proliferative response.	Placebo had 20 percent polyunsaturated, 38 percent monounsaturated fatty acids. Spontaneous and LPS-stimulated leucotriene B_4 and PGE_2 secretion did not differ among groups at baseline or after 7 weeks of treatment. IL-1 returned to baseline with 3-week washout.
ays	↑ cholesterol, LDL, HDL_2; ↓ TG by fish oil, (but olive oil ↓ cholesterol, LDL); ↓ platelet aggregation by fish oil, but olive oil ↑ aggregation.	Compliance by capsule count. Changes in control make interpretation difficult. Olive oil does not control for polyunsaturated fatty acids.
owed y	NS cholesterol, LDL, HDL; ↑ HDL_2, ↓ HDL_3, TG.	Study design doesn't allow conclusions about omega-3 fatty acid-specific effects.

Food and Drug Administration

21 CFR Part 101

[Docket No. 91N–0096]
RIN 0905–AB67

Food Labeling: Health Claims and Label Statements; Dietary Saturated Fat and Cholesterol and Coronary Heart Disease

AGENCY: Food and Drug Administration, HHS.

ACTION: Final rule.

SUMMARY: The Food and Drug Administration (FDA) is announcing its decision to authorize the use on the label or labeling of certain foods of health claims relating to an association between dietary lipids (specifically, saturated fat and cholesterol) and cardiovascular disease (specifically, coronary heart disease (CHD)). The agency has concluded that, based on the totality of the scientific evidence, there is significant scientific agreement among qualified experts that diets low in saturated fat and cholesterol may reduce the risk of heart disease. Therefore, FDA has concluded that claims on foods relating the reduction in dietary saturated fat and cholesterol to reduced risk of CHD are justified. This action is in response to provisions of the Nutrition Labeling and Education Act of 1990 (the 1990 amendments) that bear on health claims and has been developed in accordance with the final rule on general requirements for health claims, which is published elsewhere in this issue of the Federal Register.

EFFECTIVE DATE: May 8, 1993.

FOR FURTHER INFORMATION CONTACT: Paddy Wiesenfeld, Center for Food Safety and Applied Nutrition (HFS–465), Food and Drug Administration, 8301 Muirkirk Rd., Beltsville, MD 20708, 301–344–5825.

SUPPLEMENTARY INFORMATION:

I. Background

In the Federal Register of November 27, 1991 (56 FR 60727), FDA proposed to authorize the use in food labeling of health claims relating diets low in saturated fat and cholesterol to decreased risk of CHD. The proposed rule was issued in response to provisions of the 1990 amendments (Pub. L. 101–535) that bear on health claims and in accordance with the proposed general requirements for health claims for food (56 FR 60537, November 27, 1991). As amended by the 1990 amendments, the Federal Food, Drug, and Cosmetic Act (the act) provides that a food is misbranded if it bears a claim that characterizes the relationship of a nutrient to a disease or health-related condition unless the claim is made in accordance with section 403(r)(3) or (r)(5)(D) of the act (21 U.S.C. 343(r)(3) or (r)(5)(D)).

Section 3(b)(1)(A) of the 1990 amendments specifically requires that the agency determine whether claims respecting 10 nutrient/disease relationships meet the requirements of section 403(r)(3) or (r)(5)(D) of the act. The relationship between dietary lipids and cardiovascular disease is one of the claims required to be evaluated. In the Federal Register of March 28, 1991 (56 FR 12932), FDA published a notice requesting scientific data and information on the 10 specific topic areas identified. Relevant scientific studies and data received in response to this request were considered as part of the agency's review of the scientific literature on lipids and cardiovascular disease. Comments received in response to the notice and not specifically addressed in the proposed rule are summarized and addressed in this document.

Because of the extremely large volume of scientific literature on this topic, FDA limited its scientific review to those aspects of the relationship for which the strongest scientific evidence and agreement already existed: dietary intakes of total saturated fats and cholesterol relative to risk of CHD. In addition to evaluating the scientific evidence relating saturated fat and cholesterol to cardiovascular disease, the proposed rule identified qualifying and disqualifying criteria for foods, specified mandatory and optional information for health claims statements, and provided model health claims. FDA also discussed potential safety issues associated with reducing current dietary intakes of saturated fat, cholesterol, and total fat.

FDA requested written comments in response to the proposed rule and solicited comments on several issues in particular. The agency asked how to restrict the use of these health claims to foods that are appropriately included as part of healthy diets, and whether there is a need for consumer summaries.

On January 30 and 31, 1992, FDA held public hearings on all aspects of the proposed rules published in response to the 1990 amendments, including health claims for dietary saturated fat and cholesterol and heart disease (57 FR 239).

In response to its proposed health claim on lipids and cardiovascular disease, the agency received approximately 100 comments from consumers, consumer advocacy groups, State health departments, organizations of health professionals, the food industry, and Government agencies. A number of comments were received that were more appropriately answered in other documents, and these were forwarded to the appropriate docket for response.

II. Comments on the Relationship Between Dietary Saturated Fats and Cholesterol and CHD

The majority of comments supported FDA's conclusion, noting that the scientific evidence that dietary saturated fat and cholesterol increase the risk of CHD is very strong and well accepted in the scientific community. Many of these comments provided little or no detail on their reasoning. One detailed comment that supported the saturated fat and cholesterol/heart disease relationship was the report of the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology (FASEB), which evaluated recent scientific publications on this topic. The FASEB draft report was summarized by FDA in the November 27, 1991, proposal (Ref. 78). The final report was submitted to the docket as a comment (Ref. 196). The conclusions of the final LSRO report concur with previous dietary guideline recommendations that reducing intakes of saturated fat and cholesterol would lower total blood and low-density lipoprotein-cholesterol (LDL-cholesterol) levels and, thus, lower risks of CHD in the U.S. population.

A number of comments suggested modification and revision in various provisions of the proposal. A summary of the suggested changes and the agency's responses follows.

1. The agency received a number of comments focusing exclusively on dietary cholesterol as a risk factor for heart disease. Some comments suggested that the scientific evidence does not support a relationship between dietary cholesterol and blood cholesterol levels and suggested that the nutrient/disease linkage is primarily with saturated fat. The comments noted that most dietary cholesterol is not absorbed, and that individual responses to dietary cholesterol are highly variable. Conversely, many comments noted the compelling nature of the scientific evidence linking dietary cholesterol to risk of heart disease. The 1992 LSRO review of the science on this topic (Ref. 196) not only strongly supported the relationship between dietary cholesterol and increased blood

cholesterol levels but suggested that newer evidence increased the importance of dietary cholesterol as a risk factor for heart disease.

FDA agrees with those comments that suggested that there is adequate scientific evidence and significant scientific agreement that diets high in cholesterol increase the risk of heart disease. This conclusion is consistent with current dietary guidance and nutrition policy statements from the Federal Government (Refs. 29, 36, 136, and 150), the National Academy of Sciences (Ref. 20), and the recent LSRO report (Ref. 196). None of the comments that argued against such a link submitted either data or compelling logic to convince FDA that this conclusion is not correct. FDA recognize that there is some scientific disagreement about the relative importance of dietary cholesterol versus saturated fat intakes (56 FR 60730). However, there are strong and consistent data that support that saturated fat and cholesterol have independent effects on the risk of heart disease. Because the data support an independent effect for dietary cholesterol and for saturated fat, the relative importance of dietary cholesterol versus saturated fat on blood cholesterol levels and risk of heart disease really is irrelevant to the agency's conclusion that a health claim on both nutrients is appropriate. FDA recognizes that individual responses to dietary cholesterol are less consistent than to saturated fat. However, recent authoritative reviews (Refs. 20, 29, 31 through 36, 63, 71, 74, 98, 99, 129, 130, 136, 141, 150, 151, and 223) have concluded that the majority of persons in the United States will benefit from recommended dietary changes in cholesterol intake, even though the magnitude of the benefit varies among individuals.

2. Several comments stated that FDA did not address the issue of a beneficial role for dietary *cis*-monounsaturated fatty acids (MUFA's), a major source of dietary fat in the United States, in reducing the risk of heart disease. In this context, one comment noted that the Keys equation, which was used in several studies for predicting or explaining changes in blood total cholesterol based on dietary intakes of saturated and polyunsaturated fatty acids (PUFA's), was inadequate as a basis for evaluating the role of dietary lipids in reducing risk of heart disease, because it does not include a term for the amount of MUFA's. The comment further stated that, in light of newer data on possible beneficial effects of MUFA's, this equation may no longer adequately reflect the predictive value of changes in fat intakes to changes in blood cholesterol levels in the U.S. population.

The LSRO report (Ref. 196) evaluated the potential usefulness of oleic acid, the major *cis*-monounsaturated fatty acid, as a replacement for saturated fat in the American diet. The report concluded that recent research results are consistent with the conclusions that substitution of oleic acid for saturated fatty acids (SFA's) in the diet is safe and without adverse effects on blood LDL-cholesterol levels. The report stated that substitution of *cis*-monounsaturated fats for saturated fats can allow Americans to maintain customary intakes of total dietary fat without the negative effects of the more cholesterol-raising SFA's (i.e., lauric, myristic, and palmitic fatty acids). The LSRO report noted, however, that a diet high in monounsaturated fats (i.e., oleic acid) may contribute to development of obesity, a risk factor for heart disease.

FDA is aware of the recent and ongoing research efforts on the possible beneficial role of *cis*-forms of MUFA's in helping Americans to find a practical means of reducing saturated fat intake without changing total dietary fat intakes (Refs. 6, 37, 53, 57, 89, 93, 139, 144, 158, 159, 175, 180, 188, 192, 196, and 219). FDA, however, considers this issue outside the scope of this rule. In the proposed rule, the agency noted that, because of the extremely large volume of scientific research on lipids and cardiovascular disease and because of the extremely limited time constraints of the 1990 amendments, it had limited its science review to an evaluation of the relationship of saturated fat and cholesterol intakes to risk of CHD. Therefore, in both the proposed and final rules, FDA has limited the health claim to saturated fats and cholesterol.

FDA notes that the rapidly expanding science base may now, or in the future, be adequate to support that *cis*-monounsaturated fatty acids have a beneficial role in reducing blood total and LDL-cholesterol levels. However, because the question of whether this nutrient/disease relationship is appropriate for a health claim is outside the scope of this rulemaking, the question should be the subject of a petition for a health claim in accordance with the provisions of the final rule on general requirements for health claims published elsewhere in this issue of the **Federal Register**.

3. One comment suggested that novel fats that affect a surrogate marker for the disease, such as lowering of blood LDL-cholesterol, should be allowed to carry a health claim.

FDA is aware that a large amount of research and development is being done on novel fats. Novel fats are those fats that are not commonly found in the food supply. Some examples of novel fats include those fats modified by rearrangement of fatty acids in triglyceride or by the addition of a cyclic or aromatic ring to a fatty acid. (The issue of "bioavailability" of novel fats is addressed elsewhere in this issue of the **Federal Register** in the final rules on mandatory nutrition labeling, nutrient content claims, and health claims.)

FDA did not have any scientific evidence on the possible effects of specific novel fats on risk of heart disease, or on other validated surrogate markers for heart disease, in developing this final rule. Therefore, FDA has not dealt with this issue in this final rule.

III. Qualifying Nutrients

The qualifying levels for saturated fat, cholesterol, and total fat are the maximum level at which these nutrients may be present in a food if it is to qualify to bear a claim. The levels of saturated fat, cholesterol, and total fat in a food must be less than those specified in the qualifying levels for the food to be eligible.

A. Saturated Fat and Cholesterol

In the proposed rule, FDA tentatively provided that, to bear a claim associating a diet low in saturated fat and cholesterol with reduced rate of coronary heart disease, the food must be "low saturated fat," "low cholesterol," and "low fat," as those terms are defined in new § 101.62. FDA also proposed to require that the food contain 1 g or less of saturated fat per 100 g of food.

4. A number of comments recommended that claims include information about the amount of saturated fat and cholesterol beyond the information contained on the nutrition panel. Some comments recommended the use of an index or "cholesterol-saturated fat index" (CSI) that integrates known relative effects of saturated fat and cholesterol intakes in predicting increased changes in total and LDL-cholesterol levels (Refs. 202 and 203). These comments pointed out that the CSI consists of a single score or number by which it would be possible to determine the relative cholesterol-raising propensity of a given food. The comments suggested that the CSI for a given food would be calculated from the experimentally-derived formula: (1.01 × g saturated fat) + (0.05 × mg cholesterol).

One comment included a detailed listing of CSI's for a wide variety of foods, including milk with 1-percent fat, which had a CSI of 2, and butter, which had a CSI of 37.

FDA agrees with the concept that consumers should have label information presented in a manner that enables them to evaluate an individual food relative to total dietary goals. However, the agency has not included any requirement for use of a CSI index in the final rule. The comments did not provide data to show that consumers would find use of a CSI index more helpful than the nutrition information currently required on food labeling. FDA is concerned that consumers might place undue emphasis on the CSI index in purchasing decisions and not concentrate on consuming healthful diets, which include a variety of foods.

FDA considers that a consistent approach to nutrition information on food labels will be less confusing to consumers than the use of a CSI index. FDA's general approach is to provide information that allows a consumer to construct a diet that is consistent with the particular health claim and with general dietary recommendations. The use of a CSI index, however, would be inconsistent with that approach because it would likely lead the consumer to place more emphasis on the specific food than on the entire diet. In addition, the larger scientific community has not generally agreed on a particular symbol or approach, such as the CSI index, for helping consumers to identify foods that will help lower their risk of heart disease.

Thus, FDA is retaining its proposed approach with respect to the label information that must appear on foods that qualify for a health claim on lipids and heart disease.

5. A few comments suggested that foods that contain eggs or egg products should be eligible to bear the authorized health claim.

The agency agrees that a food containing eggs or egg products should not be denied a health claim for saturated fat and cholesterol and heart disease, provided that the food is "low saturated fat," "low cholesterol," and "low total fat" and meets the other qualifying requirements for a health claim on this topic. The qualifying criterion for cholesterol is based on the final concentration of cholesterol in the food product and not on the cholesterol content of ingredients. Therefore, if eggs and egg products used as ingredients do not cause a food to exceed the definition of "low cholesterol," the food may qualify for a health claim.

6. Other comments suggested that the qualifying level for the saturated fat and cholesterol content of a serving of food be made less restrictive so that a larger number of wholesome foods can qualify for a health claim. Some of the comments stated that the permissible level of 1 g of saturated fat for a serving of food should be increased to 2 g. A few comments proposed that "foods that contain 20 milligrams or less of cholesterol per serving and 2 grams or less of saturated fat should be allowed to make a health claim." Other comments asserted that the saturated fat and cholesterol/heart disease health claims should be allowed on foods that qualify for the comparative claim, "reduced cholesterol." Some comments also objected to the per 100 g density criterion for qualifying levels of saturated fat and cholesterol, suggesting that it unfairly discriminates against foods that have a useful dietary role in reducing the risk of heart disease but that, because their servings sizes are less than 100 g, exceed the qualifying criterion on a per 100-g density basis.

Based on the large number of comments that the agency received, FDA has reassessed the qualifying levels for saturated fat, total fat, and cholesterol, including the density criterion. (See the final rule on general requirements for nutrient content claims published in this issue of the **Federal Register** for a more detailed discussion. FDA incorporates that discussion by cross reference. Based on this reanalysis and on the comments received, FDA has been persuaded that the second qualifying criterion based on per 100 g is too restrictive for "low fat" and "low cholesterol" claims. (The proposed definition for "low cholesterol" did not include a per 100-g criterion.) The agency has concluded that this criterion should be modified to more directly reflect the nutrient dence foods with small serving sizes that it was designed to address. Therefore, FDA has modified the density criterion from a per 100-g basis to a per 50-g basis for foods that have a reference amount customarily consumed of 30 g or of 2 tablespoons or less. With this modification, a larger number of wholesome foods may qualify for a health claim, including more brands of breakfast cereals and cereal grain products (Ref. 222).

The agency disagrees that "reduced cholesterol" and other comparative claims should be the basis for qualifying levels of nutrients. Many foods, even after meeting the requirements for "reduced" claims, contain significant amounts of saturated fat or cholesterol. When making substitute choices among similar types of foods (e.g., deciding upon which brand of vegetable oil to purchase), comparison claims are very useful in helping consumers to make a choice. However, when putting foods together within a total dietary context, the absolute amount of nutrient present in a food is important.

7. Some comments noted that FDA's proposed definition of saturated fat (i.e., the sum of lauric, myristic, palmitic, and stearic acids) is not consistent with the most recent evidence on cholesterol-raising fatty acids. The comments suggested that the cholesterol-raising characteristics of SFA's are due almost entirely to three SFA's: lauric, myristic and palmitic fatty acids. Conversely, stearic acid, which is a significant source of SFA's in the U.S. diet, has relatively little effect on blood cholesterol levels. The comments further note that this variability in cholesterol-raising potential opens new opportunities to replace cholesterol-raising saturates with other saturates that are not cholesterol-raisers (i.e., stearic acid).

The agency agrees that specific SFA's vary in their potential for an adverse effect on blood cholesterol levels and on other atherosclerotic risk factors. In the proposed rule (56 FR 60727 at 60734), FDA acknowledged that lauric, myristic, and palmitic SFA's have the greatest effect on blood cholesterol levels, and that, in this respect, stearic acid is relatively neutral. FDA disagrees, however, that the definition of saturated fat should be limited only to the sum of lauric, myristic, and palmitic fatty acids. In the final rule on mandatory nutrition labeling published elsewhere in this issue of the **Federal Register**, and in response to comments, FDA has changed the definition of saturated fat to include the sum of all fatty acids containing no double bonds. This definition will apply to all references to saturated fat on the food label. Also, as noted in the preamble to the final rule on mandatory nutrition labeling published elsewhere in this issue of the **Federal Register**, this definition for saturated fat is consistent with dietary guidelines for diets to reduce risk of heart disease (i.e., consume less than 10 percent of calories as saturated fat; therefore, all four saturated fat (lauric, myristic, palmitic and stearic) plus less abundant saturated fats are included in the new definition.) Furthermore, FDA has noted that elevated blood cholesterol is not the only risk factor for cardiovascular disease (56 FR 60727 at 60734). Saturated fats have been implicated as possibly increasing the risk of cardiovascular disease through mechanisms other than adverse effects

on blood total and LDL-cholesterol (Ref. 20).

B. Total Dietary Fat as a Qualifying Criterion

In the proposal (56 FR 60727 at 60739), FDA proposed to prohibit health claims relating diets low in saturated fat or cholesterol to lower blood cholesterol levels and reduced risk of CHD unless the food also meets requirements for a "low" claim relative to total fat content (i.e., 3 g or less of fat per label serving size, per reference amount customarily consumed, and per 100 g). FDA notes that, while total fat is not as strongly or directly linked to increased risk of CHD as it may have significant indirect effects.

8. A number of comments supported the agency's position that a food must not only be low in saturated fat and low in cholesterol but must also be low in total fat, and that decreasing total fat intakes will generally aid in decreasing intakes of saturated fat and cholesterol. However, several comments opposed the additional "low fat" qualifying criterion, suggesting that foods recommended by public health authorities (such as fish, chicken, and lean beef and vegetable oils that are low in saturated fat and cholesterol) would not qualify for a health claim and that this would appear inconsistent with efforts to encourage an overall healthful diet.

FDA agrees that total fats are an appropriate qualifying criterion, and this provision is retained in new § 101.75(c)(2)(ii). (In the November 1991 proposed rules, FDA combined the regulations for lipids and cardiovasuclar disease (proposed § 101.73(a)) and lipids and cancer (proposed § 101.73(b)) into one section. In these final regulations, FDA has separated the two health claims into individual sections. New § 101.75 covers dietary saturated fat and cholesterol and coronary heart disease. New § 101.73 covers dietary fat and cancer.) FDA has retained this criterion because low fat foods generally help individuals in reducing their intake of saturated fat and cholesterol. In addition, excess calories, of which fat contributes more per g than the other energy nutrients, is associated with two health-related conditions (obesity and diabetes) that are risk factors for heart disease. These provisions now read in new § 101.75(c)(2)(ii): "The food shall meet all the requirements for a 'low saturated fat,' 'low cholesterol,' and 'low fat' food; * * *."

FDA agrees that lean meats, fish, and poultry, when eaten in moderation and prepared with little or no added fat, can play an important role in helping consumers to meet dietary guidelines. Meats, fish, and poultry play an important role in the U.S. dietary pattern, serving as entrees as well as rich sources of protein, bioavailable sources of many minerals, and rich sources of several vitamins. As proposed, the qualifying criteria virtually prohibit this category of foods from bearing health claims. As a result, the proposed criteria may inadvertantly interfere with the dietary guidance goals of encouraging consumption of a variety of foods and of increased use of lean meats, fish, and poultry instead of higher fat cuts.

In the final rule on general requirements for nutrient content claims published elsewhere in this issue of the **Federal Register**, FDA is defining the term "extra lean" as a claim for game meats and fish. Although this definition is not as stringent as the definition for "low fat," "low saturated fat," and "low cholesterol," it is consistent with the U.S. Department of Agriculture (USDA) definition for "extra lean" for meats and poultry.

The agency is persuaded that, to be consistent with the dietary guidence goals discussed above, health claims should be allowed on "extra lean" cuts of meat, fish, and poultry. FDA is therefore providing for saturated fat and cholesterol/CHD claims on "extra lean" game meats and fish that meet these requirements. This provision is added in new § 101.75(c)(2)(ii) which reads: "* * * except that fish and game meats (i.e., deer, bison, rabbit, quail, geese, and ostrich) may meet the requirements for 'extra lean' in § 101.62."

FDA disagrees with the comment suggesting that foods consisting entirely of fats and oils, but low in saturated fat and cholesterol, should qualify for heart disease health claims. Low fat diets are recommended in all Federal Government and National Academy of Sciences' dietary guidelines for reducing the risk of heart disease. Labeling of foods that are 100-percent fat with a message implying they are "heart healthy" is clearly inconsistent with dietary guidelines. FDA believes that the use of content claims is a more appropriate method for helping consumers make purchasing decisions about those oil products that they choose to include in their total daily diet than allowing those foods to bear health claims.

9. One comment suggested that total fat should be the basis for both the cancer and the heart disease health claims because these two diseases generally are considered together under a single dietary guidance goal for moderation in intakes of total fat and saturated fat.

The agency agrees that public health dietary guidelines generally focus on the reduction in total fat as a major, single goal when referring to both heart disease and cancer risks. However, health claims are specific for a nutrient-disease relationship. Heart disease and cancer relate to dietary factors through different mechanisms.

In the instance of CHD, dietary saturated fat and cholesterol are the major dietary risk factors because they increase blood LDL-cholesterol levels, which increase the risk of heart disease. As noted in the proposed rule (56 FR 60727 at 60739) and discussed above, total fat consumption affects risk of heart disease indirectly, through its effects on obesity and on facilitating dietary reductions in saturated fat and cholesterol. In contrast to the association between dietary fat and heart disease, the observed association between dietary fat and cancer has not been attributed to a specific type of lipid but has generally been linked to total fat intakes (see the final rule on dietary lipids and cancer published else where in this issue of the **Federal Register**.

Health claims must reflect current scientific understanding and agreement as to the basis of a diet-disease relationship. Thus, total fat is not listed as a causal dietary fat in the health claim. Instead, it is addressed as an additional criterion that must be met by a food before it may carry a health claim relating dietary saturated fat and cholesterol to risk of heart disease, because of the strong indirect effect of fat on heart disease risk. Of course, food labels may also include the claim "low fat" in addition to a health claim in accordance with the requirements for such claims, as discussed in the final rule on general requirements for nutrient content claims elsewhere in this issue of the **Federal Register**.

C. Other Qualifying Criteria

10. Some comments recommended that consumption of foods that alter other risk factors for CHD be included as qualifying nutrients relative to the fat/heart disease claim. For example, because foods high in salt or excess calories from sugars may be related to hypertension or obesity, respectively, the comments requested that limits be placed on the amount of salt or sugars that a food bearing this health claim may contain.

FDA recognizes that both hypertension and obesity are risk factors for heart disease and (see the final rule on sodium and hypertension, published elsewhere in this issue of the **Federal**

Register. As stated in the dietary guidelines, salt and sugars should be used in moderation. However, FDA believes that the arguments for making sugars content a qualifying criterion are considerably less compelling than those for total fat.

FDA has not established a Daily Reference Value for sugars because, other than dental caries, no public health concerns related to sugar have been substantiated (see final rule on Reference Daily Intakes and Daily Reference Values published elsewhere in this issue of the Federal Register). A cause-and-effect relationship between sugars intake and obesity is also not well established (Refs. 224 and 225). Conversely, the relationship of fat to obesity is based in part on the fact that fat is a more concentrated source of calories than sugars (9 calories per g versus 4 calories per g). Furthermore, new research suggests that, on a calorie-by-calorie comparison, fat calories may be more likely to be laid down as adipose (fat) tissue in the body than carbohydrate calories (including sugar) (Ref. 20).

Additionally, since saturated fat and cholesterol constitute part of the total fat content of foods, most dietary guidelines suggest that it is generally easier to reduce the target nutrients if total fat also is reduced (Refs. 20, 29, 33, 35, 36, 136, 150, and 151). High total fat intakes are also associated with the risk of cancer (see the final rule on dietary lipids and cancer, published elsewhere in this issue of the Federal Register. For these reasons, all current dietary guidelines include reduction of total fat as well as saturated fat and cholesterol when recommending dietary changes to reduce the risk of heart disease. Similar recommendations are not made for sugars (Refs. 20, 35, 136, and 151).

Thus, FDA concludes that the arguments to make sugars content a qualifying or disqualifying criterion are not convincing based on available data. FDA recognizes that all food nutrients, including sugars, have an appropriate role in the diet.

In the case of salt (and sodium), the issue is more difficult. FDA has found that sodium is a risk factor for hypertension (see the final rule on health claims for sodium and hypertension published elsewhere in this issue of the Federal Register). Furthermore, hypertension is considered to be a risk factor for cardiovascular disease, particularly for strokes and, to a lesser degree, for heart disease (Refs. 20 and 30 through 36). In choosing qualifying criteria for authorized health claims, FDA has tried to limit the number of qualifying nutrients to those nutrients that are most strongly linked to the nutrient/disease relationship, based on the current science. In the case of total fat, FDA concluded that it is appropriate to include it as a qualifying criterion because saturated fat is a subcomponent of total fat and because dietary guidelines consistently recommend moderate intakes of saturated fat, cholesterol, and total fat.

Sodium is a disqualifying nutrient for the dietary saturated fat and cholesterol/heart disease health claim, as for all health claims (i.e., as finalized, any health claim is prohibited on a food if the food contains 480 mg or more of sodium per reference amount customarily consumed, per label serving, or, if the reference amount is 30 g or less or 2 tablespoons or less per 50 g of food). The suggestion to make sodium a qualifying, rather than a disqualifying nutrient for this claim is less compelling than the argument for total fat. The link of salt to heart disease is not as direct as the link between saturated fat and cholesterol to heart disease. Dietary guidelines generally deal with sodium and fat separately. If sodium were changed from a disqualifying to a qualifying nutrient, that is, if foods were required to be low in sodium to be eligible for a saturated fat/cholesterol and heart disease claim, the number of foods that could bear such a claim would be greatly reduced. Foods excluded would include many foods in the following food categories that are generally found to be useful in meeting healthful diets: vegetable products, whole wheat breads, cereals, legume products, and some dairy products (Ref. 222). By retaining sodium as a disqualifying nutrient, not only will a much broader range of useful foods be allowed to qualify for a fat/heart disease claim, but foods in these and other food categories that contain large amounts of sodium will be disqualified. Examples of foods that will be excluded because their sodium content exceeds the disqualifying levels are certain vegetable products such as sauerkraut and some juices, many soups, and some sauces.

11. Several comments recommended that the agency drop the qualifying requirement for saturated fat in proposed § 101.73(a)(3)(iii), in which FDA proposed that the saturated fat content of the food must be less than 1 g per 100 g of food. One comment suggested that the agency instead require that the food be low in saturated fat or have "not more that 7 percent of calories from saturated fat."

The agency was persuaded by the comments that the additional density requirement (per 100 g) for saturated fat is not necessary. The agency was originally concerned that if it used only the definition for "low saturated fat" in the nutrient content claim proposal; the claim could appear on certain fats and oils. However, the agency has recognized that the requirement that a food meet the "low fat" criteria will prohibit foods that are 100 percent fat, such as oils, from bearing that health claim. The agency therefore has dropped the additional qualifying requirement for saturated fat that was in proposed § 101.73(a)(3)(iii). The agency has determined that the food or food product must meet the following qualifying criteria: "low in saturated fat, low in cholesterol, and low in total fat," as described in the rule on nutrient content claims published elsewhere in this issue of the Federal Register and stated in new § 101.75(c)(2)(ii).

IV. Safety Issues

In the proposed rule (56 FR 60727 at 60735), FDA noted that reductions in dietary intakes of saturated fat and cholesterol could result in higher intakes of other dietary components (e.g., monounsaturated and polyunsaturated fats, simple and complex carbohydrates, and commercially generated fats), because calories lost from decreased intakes of saturated fats would likely be "made up" by other energy-yielding nutrients. The availability of saturated fat and cholesterol/heart disease health claims will likely motivate manufacturers to alter the amount and type of fats added to foods, resulting in changes in composition of the U.S. food supply. As FDA discusses more thoroughly in the preamble of the final rule on general requirements for health claims, which appears elsewhere in this issue of the Federal Register, changes in consumption patterns may affect whether a food ingredient is safe and lawful under the act. Manufacturers should therefore assure themselves that such consumption changes will not affect the lawful status of the foods containing these ingredients. The agency, in its proposed rule (56 FR 60727 at 60735 to 60737), identified several areas of possible concern regarding changing American dietary patterns.

A. Trans-fatty Acids

One area of potential concern identified in the proposed rule is the potential for increased consumption of *trans*-fatty acids because of substitution of these fats for SFA's in foods. *Trans*-fatty acids (generally isomers of *cis*-monounsaturated fatty acids) are primarily constituents of commercially

hydrogenated or hardened natural vegetable oils used in formulating margarine, shortenings, and salad and cooking oils.

12. A number of comments were received, some agreeing and some disagreeing, on the agency's public health concern that *trans*-fatty acids may have cholesterol-raising characteristics, and, therefore, may increase the risk of heart disease. These concerns were raised in response to the published results of the Mensink and Katan study (Ref. 95). This study assessed the effects of a diet enriched in *trans*-fatty acid on blood lipids in 34 healthy women and 25 healthy men. The study results suggested that compared to an isocaloric diet enriched in oleic acid (a monounsaturated fat), the *trans*-fatty acid diet significantly increased LDL-cholesterol and significantly decreased high-density lipoprotein cholesterol (HDL-cholesterol) levels (two risk factors for heart disease (Refs. 1, 31, 33, 35, 48, 49, 74, 84, 112, 113, and 187)). (An evaluation of study design, results, and public health implications is found in the proposed rule (56 FR 60727 at 60736)).

In addition, the potential adverse health effects of *trans*-monounsaturated fatty acids were evaluated in the final version of the 1992 LSRO report on Lipids and Cardiovascular Disease (Ref. 196). This report states that:

> * * *until recently there was the general belief that *trans*-monounsaturates are "neutral" with respect to serum cholesterol levels. However, the recent findings of Mensink and Katan (1990) strongly suggest that these fatty acids have an adverse effect on serum lipoprotein levels, especially raising LDL-cholesterol levels. Still it hardly seems prudent to alter general dietary recommendations on the basis of a single study, albeit an excellent piece of investigation. Further carefully controlled studies thus appear to be in order before definitive recommendations can be made about *trans*-fatty acids for the American diet.

Other comments stated that "*trans*-fatty acids in foods may increase the risk of CHD equal to or greater than saturated fatty acids." Another comment suggested that "*trans*-fatty acids may increase the risk of coronary heart disease by a mechanism other than by increasing blood cholesterol." Another comment referred to *trans*-fatty acids as "deadly *trans*-fat pollution." Another comment suggested that the agency require a "warning" label for foods containing significant amounts of *trans*-fatty acids. Several comments suggested that *trans*-fatty acids should be included in the declaration of total SFA's content because they may have "cholesterol-raising" effects.

One comment on *trans*-fatty acids provided data that suggested that the *trans*-fatty acid content of some foods such as French fries was much higher than reported in commonly used food composition tables (i.e., that a medium serving of French fries from a fast food restaurant contained 7 g of *trans*-fatty acids, the upper daily limit of consumption suggested in several authoritative reports). Another comment criticized these data suggesting that proper sampling of the class of analyzed food had not been done.

One comment suggested that *cis*- and *trans*-monounsaturated fatty acids have similar metabolic actions. No data were provided in support of this comment, although it pointed out that the 1985 FASEB report on *trans*-fatty acid (Ref. 74) concluded that *trans*-fatty acids did not increase the risk of heart disease. One comment was concerned with the negative tone of the discussion on *trans*-fatty acids and suggested that the cited 1991 study by Mensink and Katan (Ref. 95) on adverse effects of *trans*-fatty acids was limited by its short duration (3 weeks), study population (healthy students), and processing techniques used to generate the hydrogenated *trans*-fatty acid isomers used in the test diets (varying catalyst and time) (Ref. 200). The comment expressed concern that the *trans*-fatty acids used in the test diets differed from those most commonly found in the U.S. food supply (i.e., different positional isomers), and that the *trans*-fatty acids may have been consumed in larger quantities in the test diets than they are generally consumed in the United States. The comment further suggested that a combination of these factors may have created a situation in which the study results suggesting that the consumption of diets enriched in *trans*-fatty acids increase blood LDL-cholesterol levels and decreased blood high density lipoprotein HDL-cholesterol; a blood cholesterol component for which low levels are associated with increased CHD risk (Refs. 1,47 through 49, 74, 75, 112, 113, and 187) were not necessarily applicable to the U.S. population. One comment referred to the report of Nestel (Ref. 177), which compared the effect of edible vegetable oil blends containing hydrogenated fatty acids on serum lipids. (The diets and study design are described in Table 1 of this document.) The results of this study showed that low saturated fat test diets containing *trans*-fatty acids from different oil sources lowered blood total cholesterol and LDL-cholesterol levels significantly as compared to control diets high in saturated fat.

Among the other comments on the study by Mensink and Katan (Ref. 95, 56 FR 60737 at 60736), was a referral to a published article written by Mensink and Katan (Ref. 201) which addressed criticisms of their 1990 study by noting that another study of longer duration (16 weeks), conducted in the same laboratory, found a similar effect on blood cholesterol levels, even after only 2 weeks on the diets (Ref. 201). One comment suggested a need for further research in the area of *trans*-fatty acids and blood cholesterol levels before policy decisions are made.

The agency agrees in general with the conclusions of the 1992 LSRO report that, while the available evidence to date is suggestive that *trans*-monounsaturated fatty acids may have LDL-cholesterol-raising characteristics, there is insufficient evidence upon which to make policy decisions at this time. FDA also notes that the requirement that foods be "low" in total fat before making a fat/heart disease health claim limits a manufacturer's ability to increase *trans*-fatty acid levels in foods, since any substitution of *trans*-fatty acids for SFA's must be done within the 3 g per reference serving size, or per 50 g, limit for total fat. This approach is unlikely to result in significantly increased levels of *trans*-fatty acids in foods qualifying for a health claim. The agency may reconsider the relationship of *trans*-fatty acid to heart disease claims at a later date if new data become available to confirm and strengthen the initial findings of an adverse effect of *trans*-fatty acids on blood LDL- and HDL-cholesterol levels. Results from well-designed scientific studies on the effect of *trans*-fatty acids at, or, slightly above, current U.S. consumption levels on blood lipids levels and on other risk factors for cardiovascular disease will aid the agency in reaching future decisions.

B. PUFA's

In the proposed rule, FDA expressed concerns about possible safety problems associated with consumption of diets enriched in polyunsaturated fats because of the substitution of these fats for SFA's (56 FR 60737 at 60736). Among concerns that FDA raised were potential adverse effects on cell membrane fluidity (a possible risk factor for cardiovascular disease (Ref. 20); decreasing levels of blood HDL-cholesterol; increase in formation of lipid hydroperoxides (oxidized LDL-cholesterol has a high atherogenic potential, Ref. 132); increasing blood

triglyceride levels (a possible risk factor for heart disease (Ref. 187); and increasing the risk of some types of cancer (see the proposed rule on dietary lipids and cancer at 56 FR 60764, November 27, 1991).

13. Many comments raised issues concerning the question of the safety of PUFA's in foods and supplements. Comments suggested that safety issues related to PUFA's included increased risk of cancer, coronary thrombosis, and osteoporosis in humans. A few comments also stated that PUFA's may adversely affect immune function. Conversely, others disagreed with the statement in the proposal that PUFA's may increase predisposition to or frequency of certain types of cancer because none of the dietary consensus documents of the Federal Government identified PUFA's as a risk factor for cancer in humans. One comment disagreed that diets enriched in PUFA's may decrease HDL-cholesterol levels but did agree with the description of results from the study by Wardlaw in Table 2 of the proposed rule (56 FR 60727 at 60764 (Ref. 144)) that, "High concentrations of PUFA's may have pharmacological effects on lowering HDL-cholesterol, however, diets containing 35 percent of calories from fat and a polyunsaturated:saturated fatty acid (P:S) ratio of less than 1.5 are not likely to lower HDL-cholesterol significantly." One comment suggested that diets high in PUFA's (greater than 10 percent of calories) cannot be achieved by the American public, so the potential safety concerns were overly emphasized.

The LSRO report on "Lipids and Cardiovascular Disease," submitted as a comment to the record, separated the evaluation of PUFA's into two categories: omega-6 polyunsaturates and omega-3 polyunsaturates (Ref. 196). Relative to linoleic acid (one of the major types of omega-6 fatty acids in the U.S. diet and an essential fatty acid), the report noted that while:

> * * * higher intakes may slightly reduce LDL-cholesterol * * * a higher consumption may increase risk for some cancers, promote LDL oxidation with the arterial wall, and possibly raise the risk for coronary thrombosis * * *. A reasonable recommendation may be to avoid both excessively low intakes of linoleic acid (below 4 percent of calories) and higher intakes (above 7 percent of calories).

Relative to the second type of PUFA's, the omega-3 fatty acids, the LSRO report noted that:

> Recommendations for increasing omega-3 fatty acids for the purpose of preventing common chronic diseases must be made with caution and only after more conclusive data are available * * *. Since these fatty acids are biologically active, they deserve intense investigation, but not premature recommendations for their consumption by the general public.

FDA agrees with the concern that high levels of intake of PUFA's have the potential for adverse effects in some persons. However, when consumed in amounts similar to current intakes, little or no risk is anticipated (Refs. 20, 29, 31, 33, 35, 74, 78, 136, and 196). Indeed, adequate intakes of essential fatty acids are needed to prevent nutrient deficiencies. By requiring that a food be low in total fat as a qualifying criterion, FDA has made it unlikely that excessively high intakes of PUFA's will be encouraged through the use of a health claim, because there is little room for manipulation of different fats within this range for total fat. Given current levels of intake of essential fatty acids by the U.S. population, deficiencies are not anticipated (56 FR 60727 at 60738; also, see document on dietary lipids and cancer published elsewhere in this issue of the **Federal Register**.

C. Other Safety Issues

14. One comment expressed concern about foods that qualify for a health claim for lipids and cardiovascular disease but that contain a nutrient that may increase the risk of cardiovascular disease or another disease or disorder. As an example, the comment suggested skim milk, which contains no or low fat and cholesterol but does contain casein. The comment suggested that casein has been reported to have atherosclerotic properties in some animals, but no data were provided to support this comment.

The basic concept of this comment, that the use of foods bearing health claims should not unduly increase the risk of disease because of the level of nutrients other than the nutrient that is the subject of the claim, is mandated by section 403(r)(3)(A)(ii) of the act. The preamble of the final rule concerning the general requirements for health claims, which appears elsewhere in this issue of the **Federal Register**, contains an extensive discussion of the agency's implementation of that section of the act through disqualifying nutrient levels.

FDA, however, disagrees with the specifics of this comment, i.e., that casein should be considered a negative component that would disqualify a food from bearing a fat/heart disease claim. FDA is aware of early research suggesting that casein has possible adverse effects on risk of heart disease (Ref. 20). However, these observations have never gained wide acceptance by the scientific community, and casein (a rich source of protein) is not considered to significantly contribute to the risk of heart disease.

V. Miscellaneous Issues

The proposal contained a number of additional provisions addressing both mandatory and optional aspects of claims about lipids and cardiovascular disease in proposed § 101.73(a)(4) and (a)(5). Proposed § 101.73(a)(4)(i) provided that a claim must state that a diet low in saturated fat and cholesterol will reduce high blood cholesterol and, thus, the risk of coronary heart disease. Proposed § 101.73(a)(4)(ii) provided that health claims must include the caveat that "some but not all individuals" would benefit from these dietary changes. Also the terminology for heart disease, blood lipid levels, and dietary fats were described in proposed § 101.73(a)(4)(iii)(A), (a)(4)(iii)(B), and (a)(4)(iii)(C). Furthermore, information on the multifactorial nature of the disease and other risk factors was included as a specific requirement in proposed § 101.73(a)(4)(iv), and optional information on the need for medical guidance and on the prevalence of heart disease in the U.S. population was provided in proposed § 101.73(a)(5)(i) and (a)(5)(ii), respectively. Many of these provisions are addressed in the following comments.

15. Some comments questioned the applicability of a claim relating diets low in saturated fat and cholesterol to reduced risk of heart disease in the general U.S. population. These comments asserted that only about 25 percent of the population may be responsive to reduction in dietary cholesterol and saturated fat. Thus, the comments argued, it would be misleading to imply that all persons would benefit. Conversely, the LSRO report concluded that "all people in the United States * * * will potentially benefit * * * from reductions in dietary saturated fat" (Ref. 196). Relative to dietary cholesterol, the LSRO report noted that "* * * avoidance of high intakes of dietary cholesterol for the whole population is prudent." Another comment suggested that the agency prescribe the term "most" individuals, persons, or people in referring to those people who may benefit from these dietary changes rather than "most but not all people."

As discussed in the proposed rule (56 FR 60727 at 60740), FDA recognizes that the beneficial effects from reduction of intakes of saturated fat and cholesterol are highly variable among individuals, particularly in terms of magnitude of effect. For this reason, FDA proposed to require that health claims make clear that the effects described in the claim

are likely to be realized by "some but not all persons" (proposed § 101.73(a)(4)(ii)). At the same time, FDA does not wish to imply that a health claim on dietary lipids and heart disease in accordance with this rule is not useful information for the general population. Current dietary guidelines and the LSRO report cited above conclude that, even if responses among individuals are variable in magnitude, the majority of the population, including persons with normal blood cholesterol levels, will benefit from these dietary goals (Refs. 20, 29 through 36, 74, 136, and 151). Given the strong scientific agreement that the majority of persons in the U.S. will benefit from a reduction in intake of saturated fat and cholesterol, FDA has concluded that the proposed term "some persons but not all" is too conservative. FDA has thus not included any requirement for indicating that the nutrient/disease relationship is limited to "some persons but not all" in the final rule. Therefore, new § 101.75(c)(2)(i)(A) reads: "The claim states that diets low in saturated fat and cholesterol 'may' or 'might' reduce the risk of heart disease;".

16. Several comments recommended that the agency require that health claims include a statement on seeking medical advice for persons with multiple risk factors for heart disease. These comments suggested that the majority of the population at risk of cardiovascular disease may require medical advice and may need a combination of medication and diet and lifestyle changes. For these persons, adopting a diet low in saturated fat and cholesterol may not substitute for aggressive medical intervention.

FDA agrees that persons with blood LDL-cholesterol levels in the moderate to high risk ranges and with multiple risk factors for heart disease should seek medical advice. However, as noted above, dietary goals for intakes of saturated fat and cholesterol have been recommended for the general population as well as for persons with elevated blood cholesterol levels because of findings of benefit across the entire range of blood cholesterol levels (Refs. 31 and 33). FDA is concerned, therefore, that to require a statement that persons seek medical advice and guidance as part of the health claim might give the erroneous impression to consumers that there is no benefit for them in making the recommended dietary changes unless they have been identified as high risk patients. For this reason, FDA is not persuaded to change the status of information on medical advice from an optional to a mandatory requirement. Thus, the agency is retaining this provision as an optional statement in new § 101.75(d)(7), which states:

> The claim may state that individuals with elevated blood total- or LDL-cholesterol should consult their physicians for medical advice and treatment. If the claim defines high or normal blood total- or LDL-cholesterol levels, then the claim shall state that individuals with high blood cholesterol should consult their physicians for medical advice and treatment.

17. The agency proposed in § 101.73(a)(4)(iv) that the health claim may state that CHD is a multifactorial disease and listed major risk factors for the disease that may be used in the claim. This provision was worded so as to suggest that providing the above information was optional. However, this provision was included among the specific requirements in § 101.73(a)(4).

The agency received comments that both supported and opposed FDA requiring that any health claim describe CHD as a multifactorial disease. Several comments suggested that the multifactorial nature of the disease should be referred to indirectly, while other comments suggested that these multiple factors should be required to be identified in the health claim. Some comments identified a number of modifiable dietary risk factors for cardiovascular disease not included among those listed the proposed health claims such as: sodium (56 FR 60825), fiber (56 FR 60582), and antioxidant vitamins (56 FR 60624). Other comments recommended that the agency require that the most important risk factors for CHD, elevated LDL-cholesterol, high blood pressure, and cigarette smoking, be listed.

FDA recognizes that its proposal was inadvertantly ambiguous about whether the fact that CHD is a multifactorial disease would be a required element of the health claim on dietary lipids and this disease. As pointed out in the proposal (56 FR 60726 at 60740), given the multiple dietary, genetic, and lifestyle risk factors for this disease, consumers would be misled if they were to think that dietary factors are the only risk factors. Given this fact, FDA has concluded that the multifactorial nature of the disease should be a required element (§ 101.75(c)(2)(i)(E)).

The issue that is raised as a result is how the significant risk factors should be presented. FDA is concerned that encouraging an unrestricted listing of risk factors for heart disease could result in the listing on food labels of risk factors with relatively little importance or minimal scientific support or could be used to bypass other label requirements. For example, some comments listed several nutrient risk factors for heart disease, including sodium intake. While FDA is authorizing the use of sodium/hypertension health claims, the agency has not been presented with evidence that sodium intake is a risk factor for heart disease. A claim characterizing the relationship between sodium and heart disease is a health claim and would misbrand a food under section 403(r)(1)(B) of the act unless it is specifically authorized by the agency. Thus, the comments suggested that some would use a list of factors as a backdoor means of making unauthorized health claims. As a result, FDA concludes that only the significant risk factors should appear as part of a health claim. For example, those factors that identify the populations that are at risk, where the general population is not at risk, are appropriate for inclusion in the claim. Listing risk factors that are not significant would be false or misleading and could, as explained above, misbrand the food under section 403(r)(1)(B) of the act.

While FDA has decided that the fact that coronary heart disease is multifactorial should be a mandatory element of nutrition labeling, it has also decided that the specific risk factors need not be. As discussed below in conjunction with model health claims, FDA has received numerous comments that the shorter health claims are, the more likely it is that they will be used and understood. Therefore, given the information that it is requiring, FDA has decided, that on balance, it is not necessary to include the significant risk factors as mandatory elements of a claim.

The listing of risk factors provided in proposed § 101.73(a)(4)(iv) represented scientific consensus as to the most significant factors for heart disease. In this final rule, FDA has redesignated the list of risk factors in proposed § 101.73(a)(4)(iv) as new § 101.75(d)(1). This section provides a list of the factors that, based on general scientific agreement, are the major factors for heart disease. The agency has also provided that any list of risk factors included as part of a health claim may include one or more of these factors but must be limited to the factors on this list. Thus, new § 101.73(d)(1) states that:

> The claim may identify one or more of the following risk factors in addition to saturated fat and cholesterol about which there is general scientific agreement that they are major risk factors for this disease: a family history of coronary heart disease, elevated blood LDL-cholesterol, excess body weight, high blood pressure, cigarette smoking, and long-term physical inactivity.

18. Other comments pointed out that, while excessive intake of some nutrients such as fat may be harmful, there are also minimum intake levels which are essential. Some of the comments suggested that the agency identify minimum thresholds levels for SFA's, MUFA's, PUFA's, total fat, and other dietary nutrients below which intakes should not drop. The comments expressed concern that intakes below these levels would increase risk of nutrient deficiencies.

FDA recognizes that there are intake levels for nutrients below which there may be a risk of nutrient deficiencies that could present a risk of adverse effects. FDA disagrees, however, that these levels should be included in the health claim on dietary saturated fat/cholesterol and heart disease. In the proposed rule for a health claim on lipids and cardiovascular disease and as stated in the proposed rule on dietary lipids and cancer, FDA noted that:

> The requirement of linoleic acid to avoid essential fatty acid deficiency is 1 to 2 percent of total calorie intake. Currently, the average linoleic acid consumption in the U.S. ranges between 5 and 10 percent of total calorie intake, and deficiencies of essential fatty acids are rare in the U.S. Thus, a reduction of total fat consumption from the current 36 to 37 percent of total calorie intake to about 30 percent is not likely to cause essential fatty acid deficiencies in the general population.

(56 FR 60764 at 60712)

Furthermore, as previously noted in the response to comment 14 of this document, the reduction of saturated fat intakes to meet dietary goals for reduction in risk of heart disease is likely to result in increased intakes of PUFA—the source of the essential fatty acid, linoleic acid. Thus, FDA concludes, as was also concluded in several authoritative reports (Refs. 20, 29, 35, 136, and 150), that there is little likelihood of nutritional deficiencies resulting from changes in U.S. dietary patterns in response to health claims relative to saturated fat/cholesterol and heart disease.

19. One comment suggested that health claims not be allowed on foods that have been modified to meet the "low fat," "low saturated fat" or "low cholesterol" requirements unless the foods are nutritionally equivalent to the unmodified versions of those foods. FDA rejects this comment. The issue of the effects of a failure to maintain nutritional equivalency are fully addressed by § 101.3(e) of FDA's regulations, and in the final rule on standardized foods named by use of a nutrient content claim and a traditional standardized term, published elsewhere in this issue of the Federal Register. As long as a food meets the requirements of those regulations, § 101.14, and § 101.75, it may bear a health claim on the relationship of saturated fat and cholesterol and coronary heart disease.

20. One comment asked the agency to reconsider its position that health claims are inappropriate for foods intended to be consumed by infants and toddlers of less than 2 years of age; second, to reconsider the amount of total fat, saturated fat and cholesterol that meet requirements for health for infants and toddlers; third, to reconsider the age when infants and toddlers should start to consume "low fat" diets. The comment recommended that low saturated fat, low cholesterol, and low fat diets should be extended to even earlier ages, and that the percent of calories from fat for infants and toddlers should be less than 30 percent to reduce obesity, a risk factor for heart disease. The comment did not submit scientific data to support the proposition that a reduction in heart disease would occur if infants and toddlers consumed low fat diets (i.e., less than 25 percent of calories) earlier than 2 years of age.

FDA disagrees with the comment. In the 1990 amendments, Congress indicated that, if FDA's decision on a health claim petition deviated from recommendations of the Federal Government, those differences should be justified (section 403(r)(4)(C) of the act). The agency based its conclusions on the report from the National Cholesterol Education Program (NCEP) on population strategies for healthy children and adolescents (56 FR 60727 at 60731 (Ref. 34)). This report stated that general dietary recommendations for diets low in saturated fat, cholesterol, and total fat should be extended to cover toddlers and children 2 years and older. FDA has seen no compelling evidence to counter the conclusions of the NCEP report.

21. Several comments supported the agency's proposed limitation in proposed § 101.73(a)(4)(iii) on interchangeable terms for the disease, for lipids levels, and for the nutrients involved. Another comment suggested that the term "low density lipoprotein cholesterol" or the term "LDL-cholesterol" be used in place of the term "total blood cholesterol."

FDA agrees that the term "LDL-cholesterol" is more precise than the term "blood total cholesterol," but disagrees that it should be used in place of the term "total blood cholesterol" in § 101.75(d)(2) of the final rule. FDA, in proposing the term "total blood cholesterol" was using language commonly used in dietary guidance materials at the time of the proposal. Since the publication of the proposal, the National Heart, Lung and Blood Institute (NHLBI) of the National Institutes of Health (NIH) held a consensus conference on Triglycerides, High Density Lipoprotein, and Coronary Heart Disease in February 1992 (Ref. 187). As a result of that conference, a consensus panel draft report was published reconfirming that high levels of blood LDL-cholesterol are associated with high risk of CHD. The consensus conference panel draft report also concluded that low levels of another blood cholesterol component, HDL-cholesterol, in conjunction with high levels of LDL-cholesterol, were associated with a higher risk of heart disease. These two different cholesterol transport components of blood cholesterol when considered in combination are better predictors of risk than when considered independently.

The agency believes that the term "blood total cholesterol" should be retained to minimize consumer confusion, since that term is used in dietary guidance materials and many consumers know their blood total cholesterol levels. However, the agency believes that consumers will eventually learn that high LDL-cholesterol levels are strongly associated with risk of heart disease and are reduced by diets low in saturated fat and cholesterol in most people. The agency has therefore specified in new § 101.75(d)(2) that the term "LDL-cholesterol" may optionally be used in addition to the term "blood cholesterol," and states: "The claim may indicate that the relationship of saturated fat and cholesterol to heart disease is through the intermediate link of "blood cholesterol" or, "blood total- and LDL-cholesterol."

In other respects, the agency is carrying forward the terminology from the proposal in new § 101.75(c)(2)(i)(B), the agency is limiting the terms used to specify the disease to heart disease or coronary heart disease. This provision is consistent with proposed § 101.73(a)(4)(iii)(A). Furthermore, in new § 101.75(c)(2)(i)(C), the agency retains the limitations on specifying the nutrient in proposed § 101.73(a)(4)(iii)(C). However, § 101.75(c)(2)(i)(C) states that: "In specifying the nutrient, the claim uses the terms 'saturated fat' and 'cholesterol,' and lists both;".

22. One comment requested that health claims relating to lipids and cardiovascular disease be allowed for fruits and vegetables, which are naturally low in saturated fat, total fat, and cholesterol.

FDA agrees that fruits and vegetables should be allowed to bear appropriate health claims. The agency notes that because most fruits and vegetables are naturally low in saturated fat and do not contain cholesterol, they will meet the qualifying criterion of new § 101.62 for "low saturated fat," "low cholesterol," and "low total fat," and thus will qualify under § 101.75(c) to bear this claim.

FDA advises that it has made a couple of additional minor changes in § 101.75. The agency has added § 101.75(a)(1), which, consistent with other regulations that the agency is adopting that authorize health claims, defines some of the terms in the regulation. These definitions are consistent with generally accepted science and with the discussion in the proposal. In addition in § 101.75(d)(5), FDA has added the National Institutes of Health and "Nutrition and Your Health: Dietary Guidelines for Americans" (Ref. 29) in recognition that both are sources of information on the number of Americans with heart disease.

VI. Model Health Claims

23. Several comments suggested that the model health claims should be reduced in length. Some suggested that health claims should follow examples established by the Surgeon General's office, keeping the health claim in a precise, easily understandable text. One manufacturer submitted model health claims and examples of labeling. One comment submitted an example of a possible health claim: "Eating a healthful diet low in fat, saturated fat and cholesterol can help reduce the risk of heart disease." Another comment suggested that the health claim should state: "This ———— can be part of a total diet low in saturated fat and cholesterol, which can reduce risk of heart disease. Use in place of more saturated fats as part of a diet low in total fat. Contains ———— grams of saturated fat, ———— grams of total fat per serving." Another comment recommended an additional statement to be added to the health claim: "In vitro and animal data are often useful for formulating research hypotheses, but can be inappropriate and unreliable for making public policy."

FDA agrees with the comments that, to the extent possible, the model health claims should be shortened and made more understandable. They are more likely to be used by manufacturers if they take up as small an amount of label space as possible. Consumers will be more likely to read messages if they are stated simply and succinctly. However, section 403(r)(3)(B)(iii) of the act requires that health claim regulations ensure that claims accurately represent the nutrient/disease relationship and its significance and enable consumers to understand the information and its significance in the context of the total daily diet. Thus, there are constraints on FDA's authority to permit claims to be abbreviated.
